INFORMATION  
ENGINEERING  
UNIVERSITY OF PADOVA

Joint work w/ Bruno Sinopoli (CMU),  
Massimo Franceschetti (UCSD),  
Kameshwar Poolla and Shankar Sastry (UCB)

KTH, 14/09/2007

## Drive-by-wire systems

## Swarm robotics

## Smart structures: adaptive space telescope

## Wireless Sensor Networks

## Traffic Control: Internet and transportation

## Smart materials: sheets of MEMS sensors and actuators

**NCSs: physically distributed dynamical systems  
interconnected by a communication network**

# NCSs: what's new for control?

## Classical architecture: Centralized structure

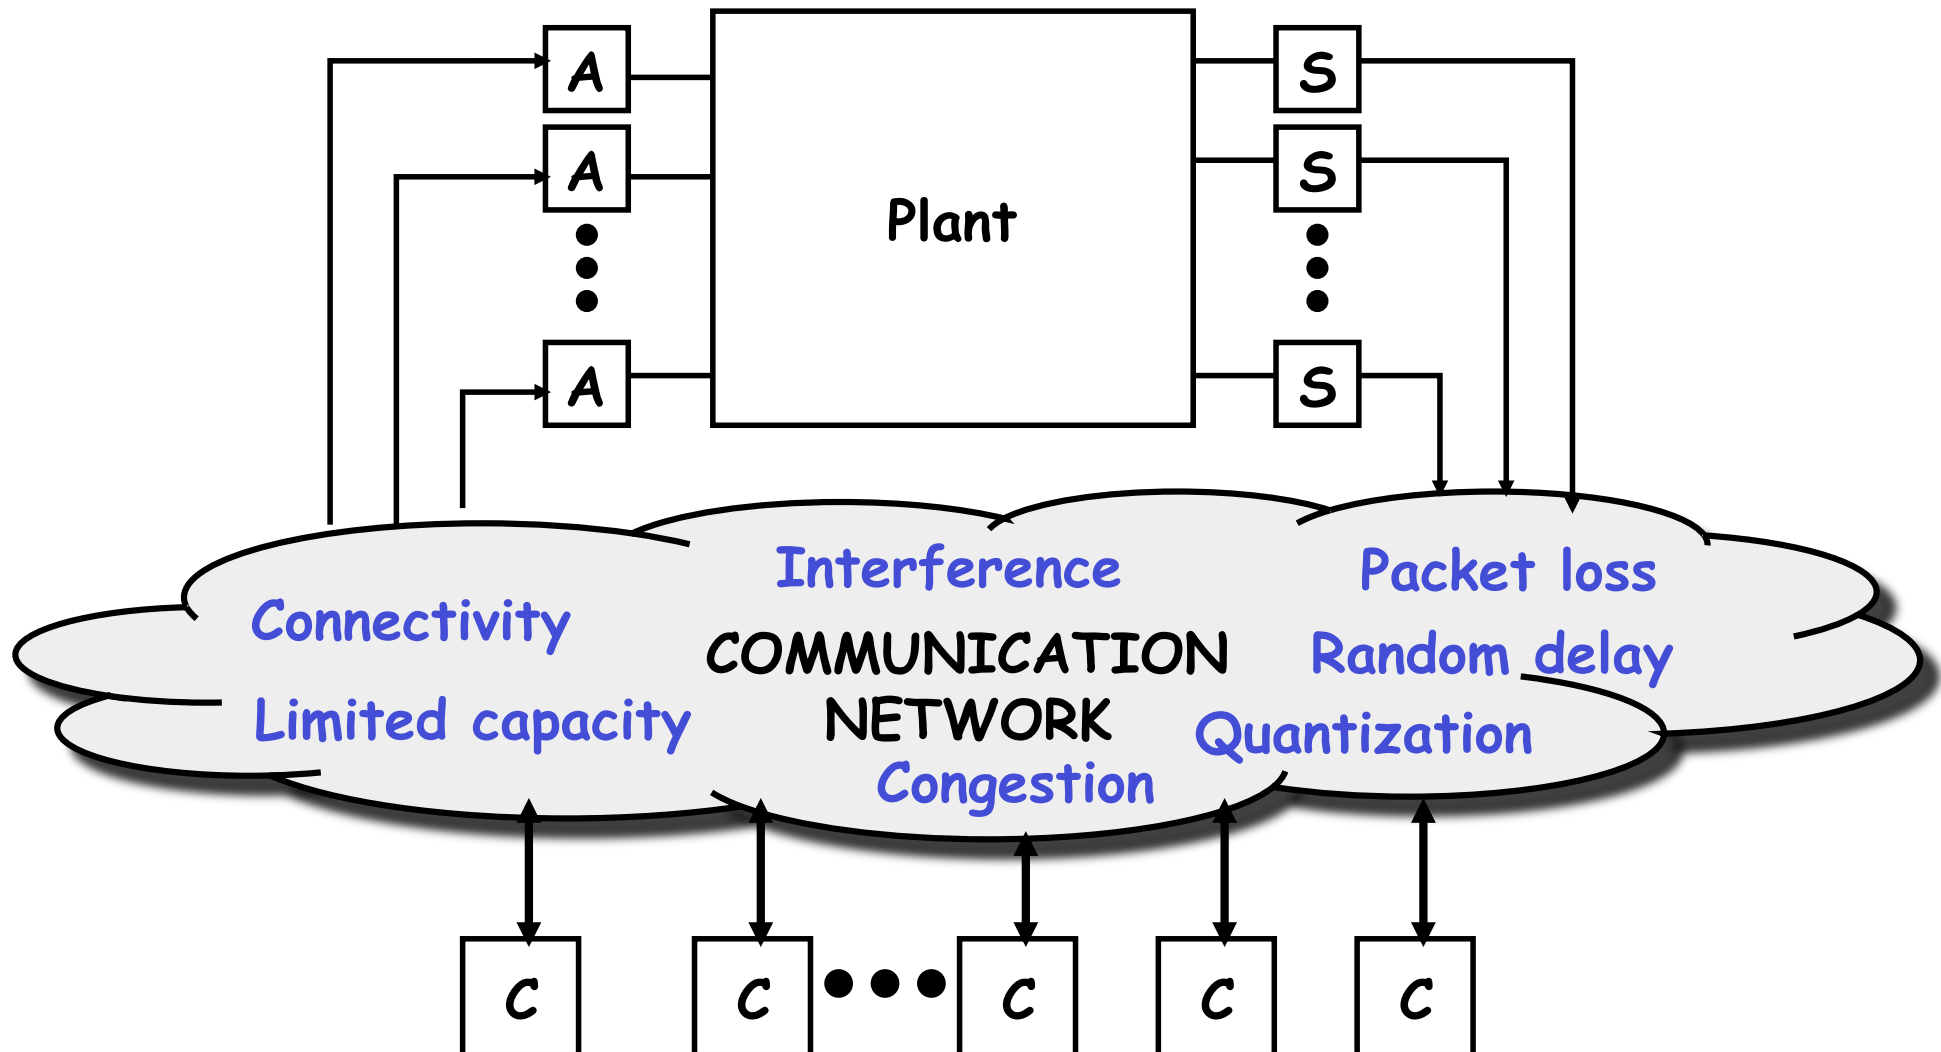

# NCSs: what's new for control?

NCSs: Large scale distributed structure

# Interdisciplinary research needed

## COMMUNICATIONS ENGINEERING

- Comm. protocols for RT apps
- Packet loss and random delay
- Wireless Sensor Networks
- Bit rate and Inf. Theory

## SOFTWARE ENGINEERING

- Embedded software design
- Middleware for NCS
- RT Operating Systems
- Layering abstraction for interoperability

## NETWORKED CONTROL SYSTEMS

## COMPUTER SCIENCE

- Graph theory
- Distributed computation
- Complexity theory
- Consensus algorithms

# Interdisciplinary research needed

<small>Nom EN 153 May 1990 Refrigerator Label Directive 94/2/EC</small>	

- Building thermodynamics model identification
- Sensor selection for identification
- Optimal sensor placement

# NCS example: Distributed Localization & Tracking

## FIRE Eye From Moteiv

- Rescue system with wirelessly networked sensors and electronic maps
- Delivers critical information to firefighters during an emergency
- Cooperation between Chicago Fire Department, Moteiv and UC Berkeley engineers
- Monitors occupancy, smoke, light and fire
- Tracks emergency crew inside the building and displays the details inside the firefighter's mask

Technology for Innovators™

TEXAS INSTRUMENTS

- Indoor radio signal modeling
- Real-time localization
- Distributed tracking
- Coordination

# NCS example: Coordinated Robotics & WSNs

Motion Capture  
System  
(virtual GPS)

Wireless Sensor  
Networks  
(Berkeley Tmote  
Sky)

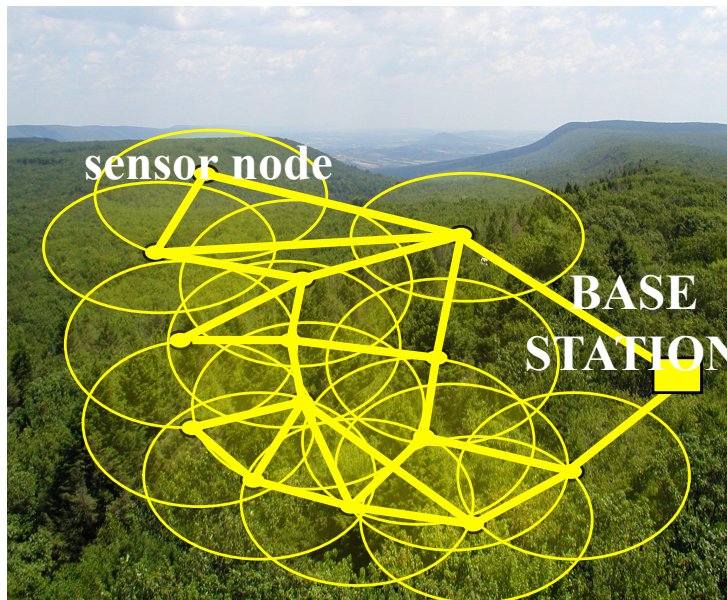

Mobile vehicles  
(EPFL e-puck)

- Coordination & consensus algorithms
- Integration mobile nodes w/ static nodes
- WSN-based localization & navigation

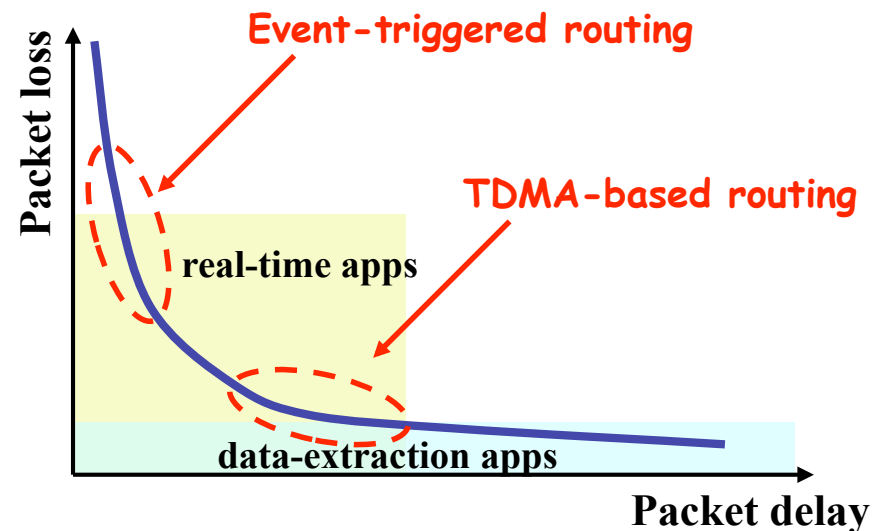

# Motivating example: wireless sensor networks

## Forest Temperature Monitoring (data-extraction application)

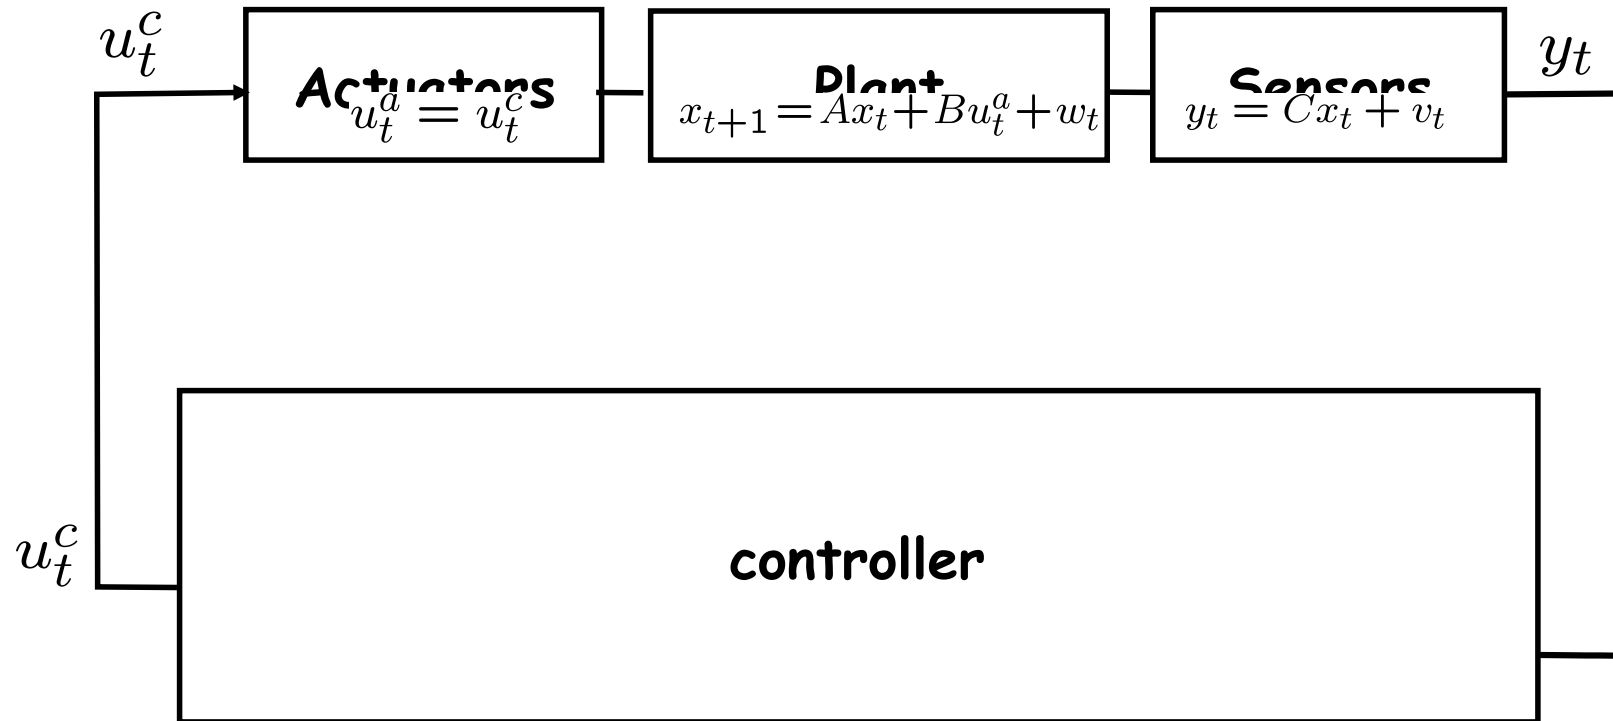

## Wildfire detection & tracking (real-time application)

- Can we design **optimal estimators** that compensate for random delay and packet loss ?
- What is the performance if we have **packet arrival statistics** ?
- How can we **compare** different communication/routing protocols in terms of estimation performance ?

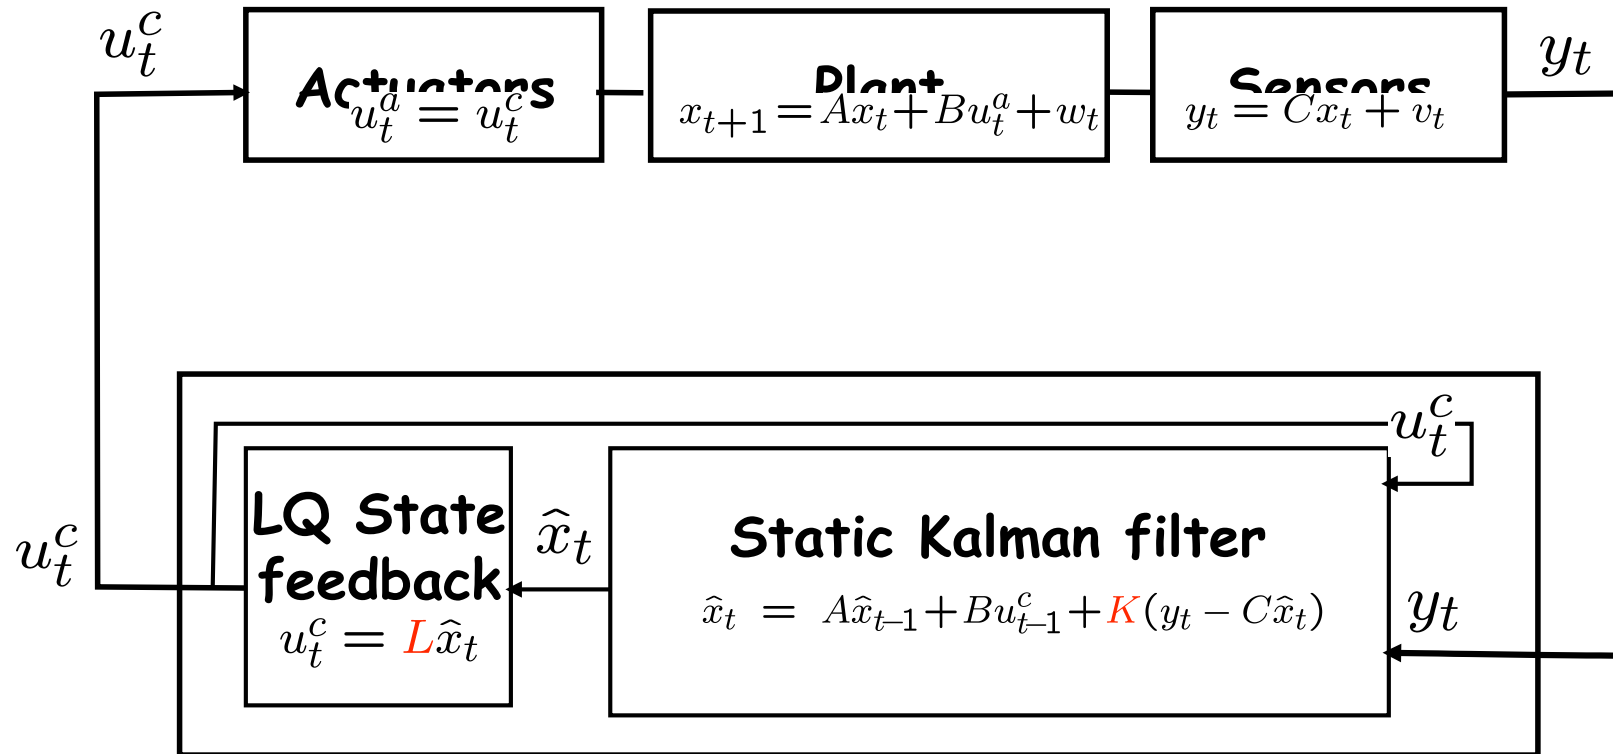

# Optimal LQG

$$\min_{u_1^c, \dots, u_T^c} J = \sum_{t=1}^T E[x_t^T W x_t + u_t^T U u_t], \quad T \rightarrow \infty$$

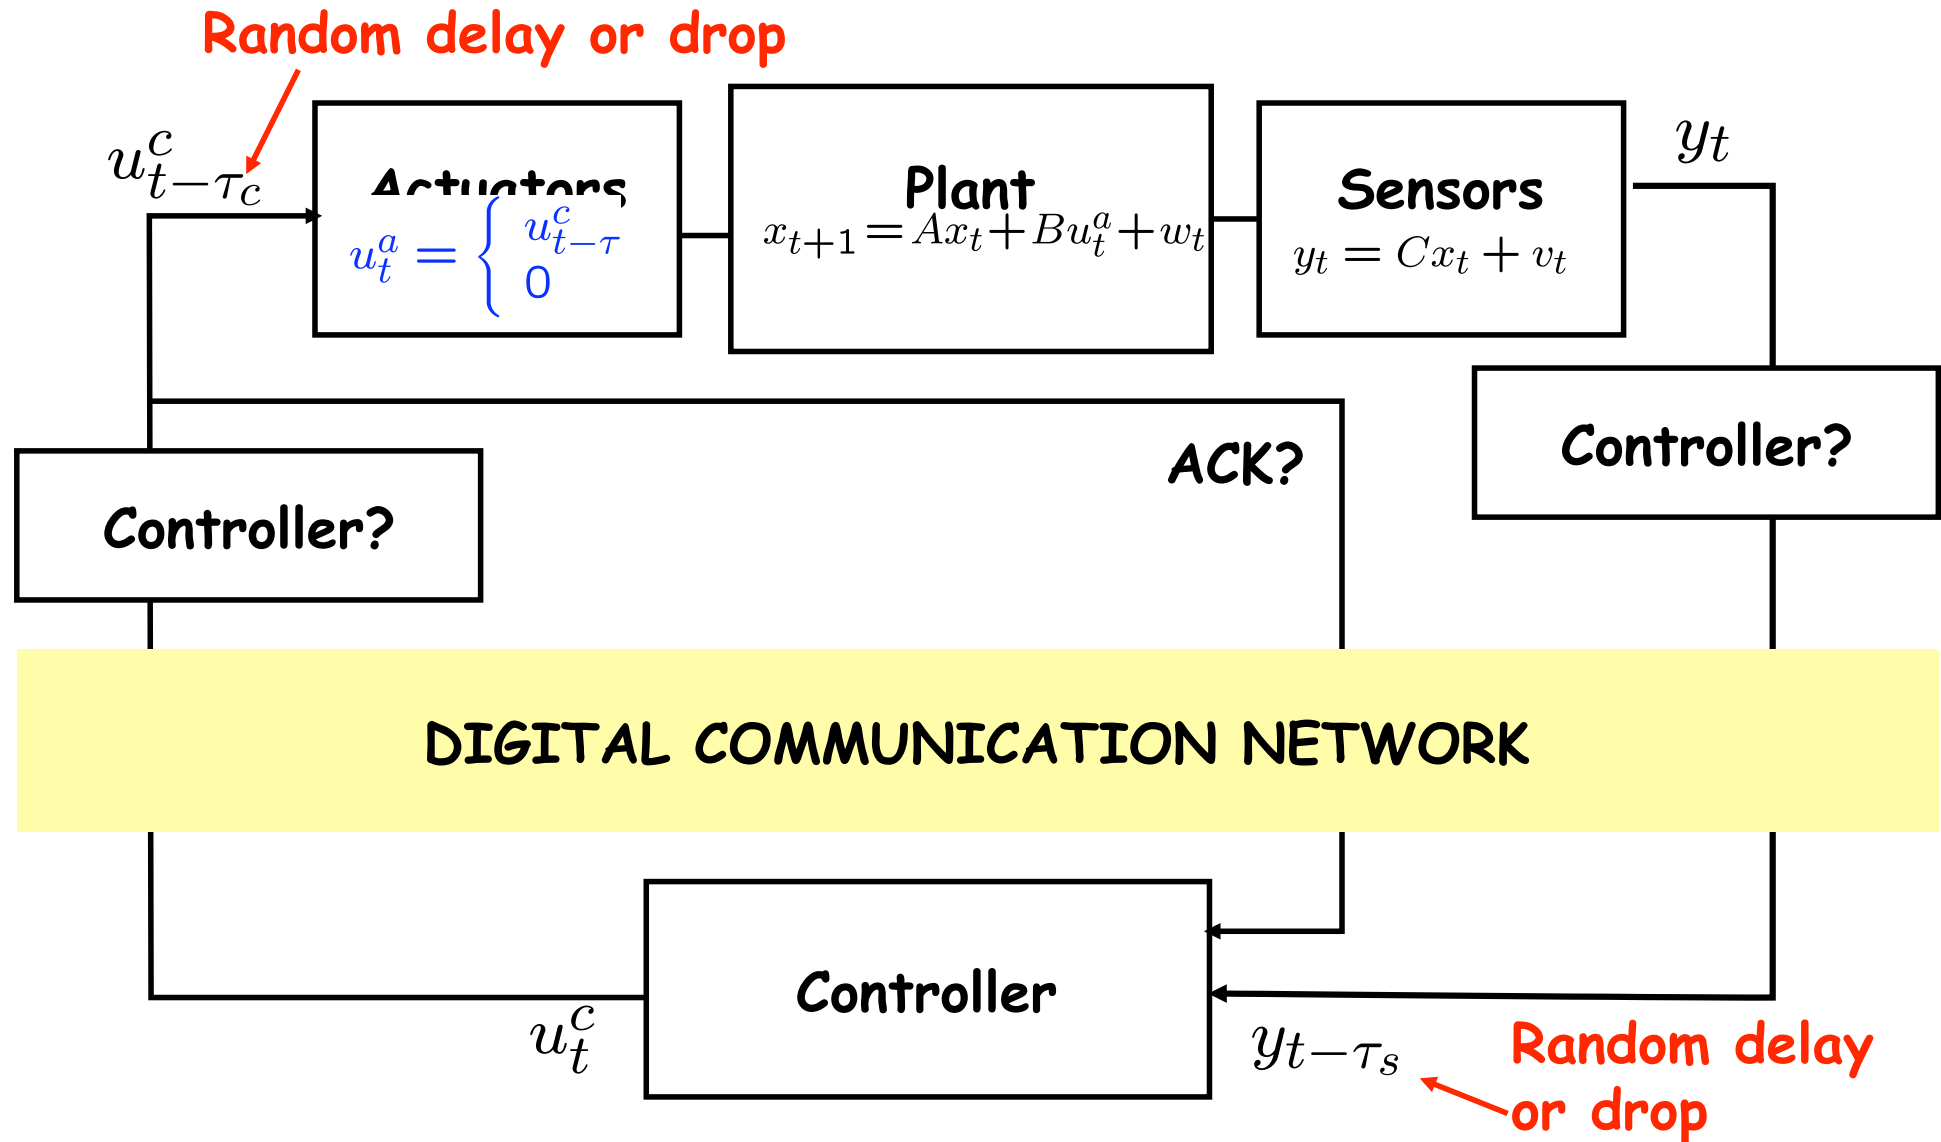

**Sensors and actuators are co-located, i.e. no delay nor loss**

# Optimal LQG

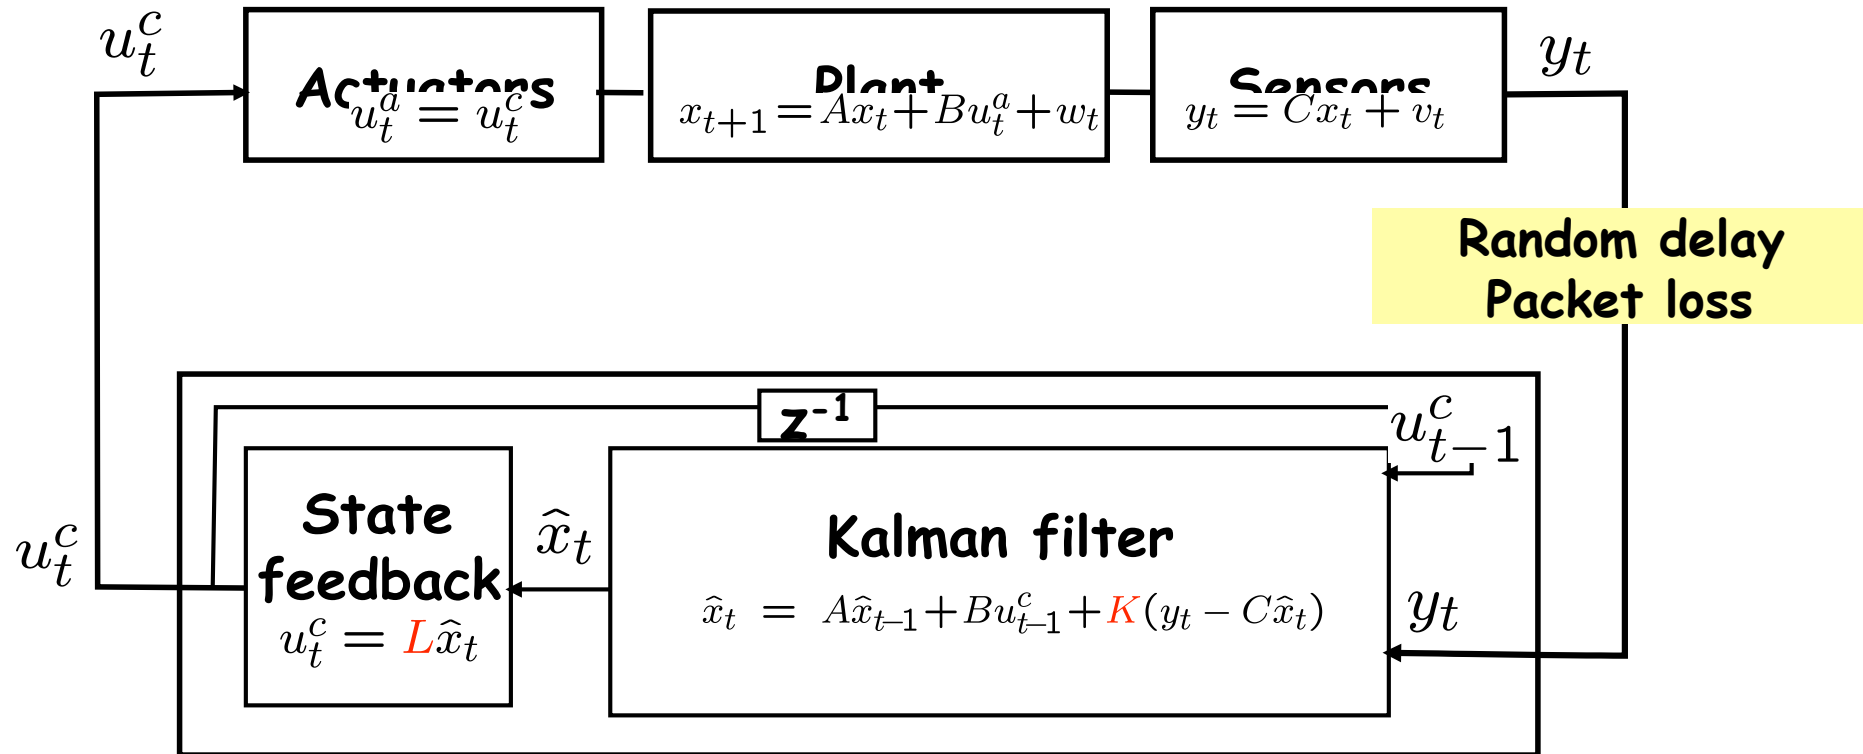

1. Separation principle holds: Optimal controller = Optimal estimator design + Optimal state feedback design
2. Closed Loop system **always stable** (under standard reach./det. hypotheses)
3. Gains **K,L** are constant solution of Algebraic Riccati Equations

# Optimal LQG control over DCN

# Some consideration on the separation principle

$$\hat{x}_t = E[x_t | y_t, y_{t-1}, \dots, y_0, u_{t-1}^a, \dots, u_1^a]$$

if  $(u_{t-1}^a, \dots, u_1^a)$  known  $\implies e_t = x_t - \hat{x}_t = f(y_t, y_{t-1}, \dots, y_1, y_0)$

# Modeling of Digital Communication Network (DCN)

ATM	384 bits	40 bits
Ethernet	>368 bits	112 bits
Bluetooth	>499 bits	~100 bits
Zigbee	<1000 bits	128 bits

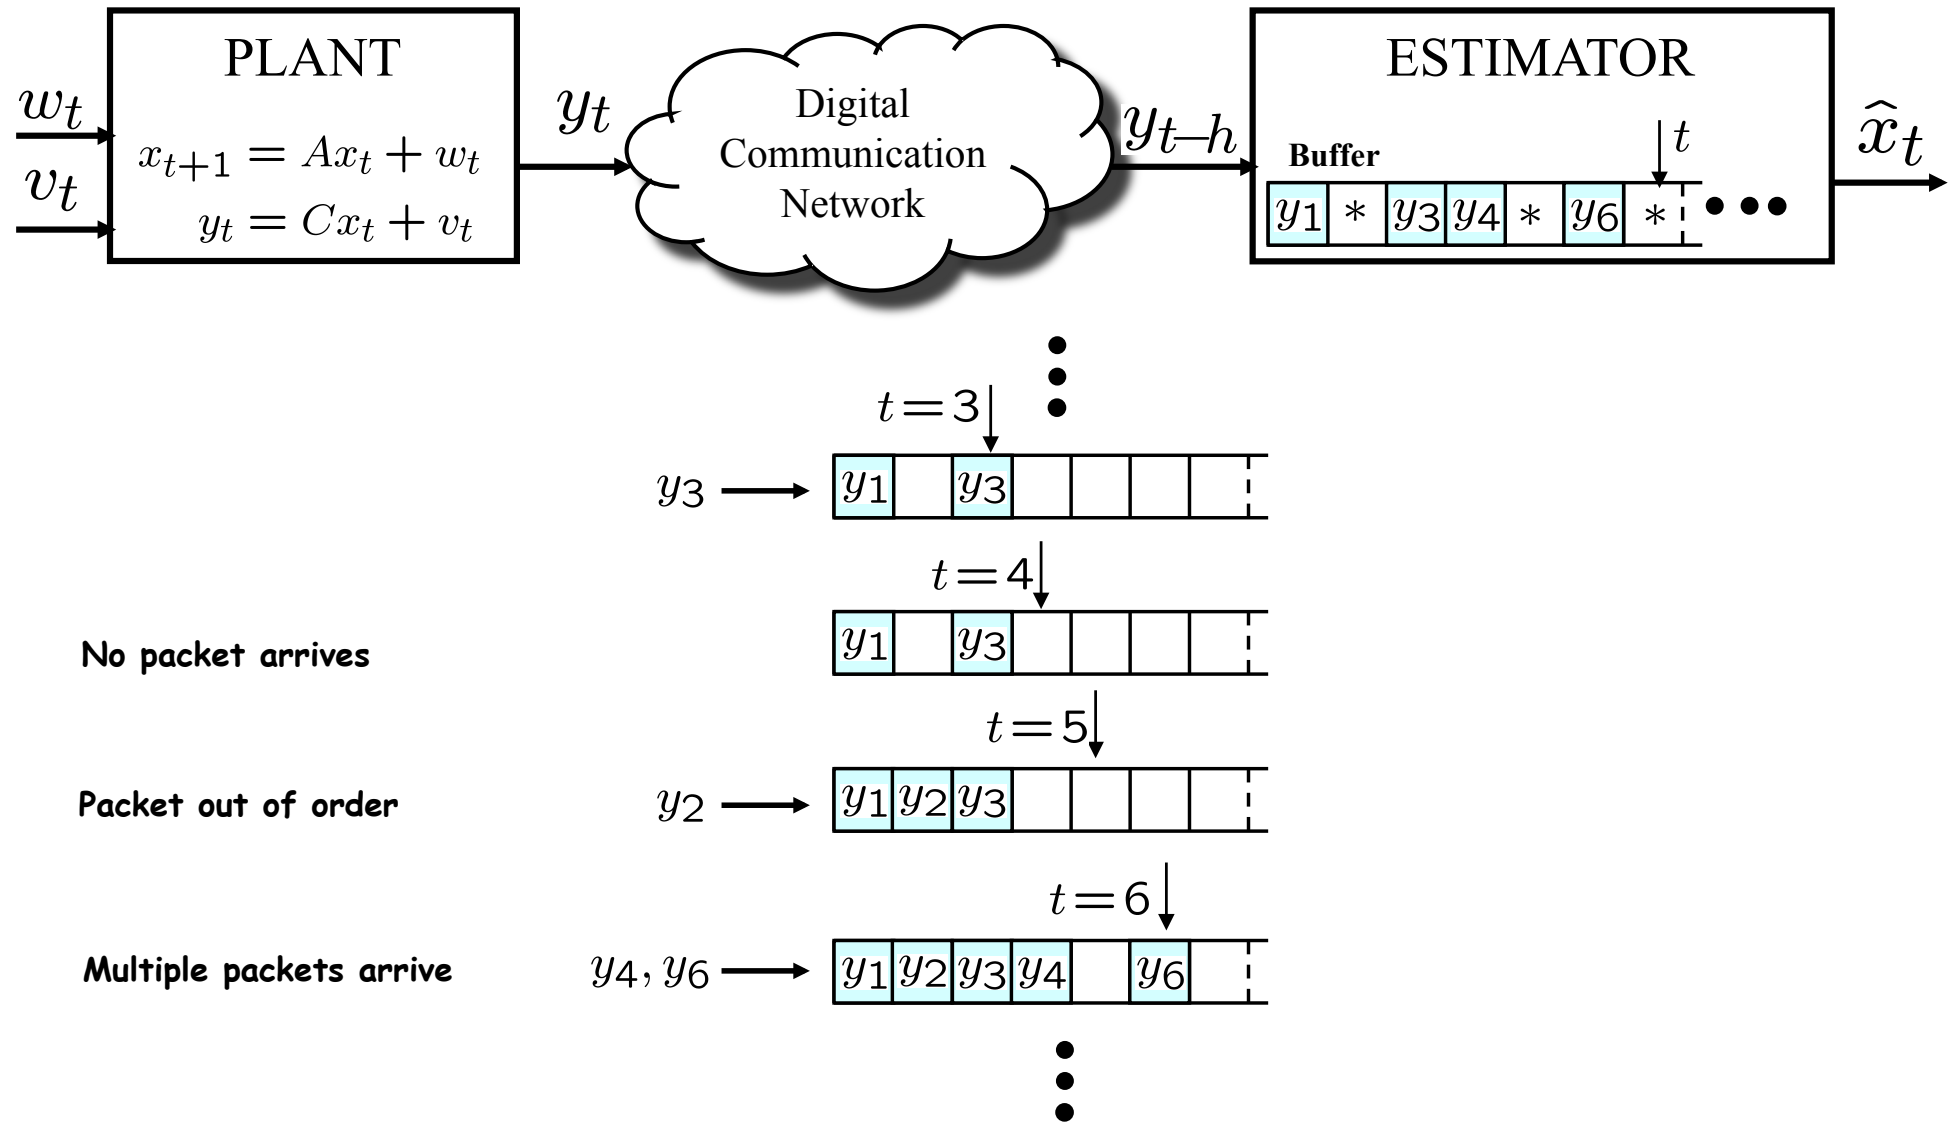

## Assumptions:

- (1) Quantization noise  $\ll$  sensor noise
- (2) Packet-rate limited ( $\neq$  bit-rate)
- (3) No transmission noise (data corrupted = dropped packet)
- (4) Packets are time-stamped

**Random delay  
&  
Packet loss  
at receiver**

# Estimation modeling

$$\hat{x}_t = \mathbb{E}[x_t | \{y_k\} \text{ available at estimator at time } t]$$

$$\gamma_k^t = \begin{cases} 1 & \text{if } y_k \text{ arrived before or at time } t, t \geq k \\ 0 & \text{otherwise} \end{cases}$$

$$\tilde{y}_k = \gamma_k^t (Cx_k + v_k) = C_k^t x_k + u^t$$

**Kalman  
time-varying  
linear system**

$$\hat{x}_t = \mathbb{E}[x_t | \tilde{y}_1, \dots, \tilde{y}_t, \gamma_1^t, \dots, \gamma_t^t]$$

# Minimum variance estimation

# Minimum variance estimation

$\gamma = 0$

$$\begin{aligned}\hat{x}^+ &= A\hat{x} \\ P^+ &= APA^T + Q\end{aligned}$$

Lyapunov Equation  
(unstable)

$\gamma = 1$

$$\begin{aligned}\hat{x}^+ &= A\hat{x} + K_k^t(\tilde{y}_k^t - CA\hat{x}) \\ P^+ &= APA^T + Q - APC^T(CPC^T + R)^{-1}CPA^T\end{aligned}$$

Riccati Equation

$$\hat{x}^+ = A\hat{x} + K_k^t(\tilde{y}_k^t - CA\hat{x})$$

$$P^+ = APA^T + Q - APC^T(CPC^T + R)^{-1}CPA^T$$

Riccati Equation  
(stable)

# Minimum variance estimation

# Properties of Optimal Estimator

- Optimal for any arrival process
- Stochastic time-varying gain  $K_t = K(\gamma_1, \dots, \gamma_t)$
- Stochastic error covariance  $P_t = P(\gamma_1, \dots, \gamma_t)$
- Possibly infinite memory buffer
- Inversion of up to  $t$  matrices at any time  $t$

$$\gamma_k^t = \text{cost}, \quad t \geq k + \tau_{max}$$

$$\tau_{max} = N, \quad \text{delay}$$

$$\hat{x}_{t-N+1|t-N}^{t-1} \triangleq \hat{x}$$

$$P_{t-N+1|t-N}^{t-1} \triangleq P$$

$$\hat{x}^+ = A\hat{x} + \gamma_{t-N}^t PC^T (CPC^T + R)^{-1} (\tilde{y}_{t-N}^t - CA\hat{x}),$$

$$P^+ = APA^T + Q - \gamma_{t-N}^t APC^T (CPC^T + R)^{-1} CPA^T$$

# Minimum variance estimation

$$\gamma = 0$$

$$\begin{aligned}\hat{x}^+ &= A\hat{x} \\ P^+ &= APA^T + Q\end{aligned}$$

**Lyapunov Equation**  
(unstable)

$$\gamma = 1$$

$$\begin{aligned}\hat{x}^+ &= A\hat{x} + K_k^t(\tilde{y}_k^t - CA\hat{x}) \\ P^+ &= APA^T + Q - APC^T(CPC^T + R)^{-1}CPA^T\end{aligned}$$

**Riccati Equation**  
(stable)

$$\gamma = 0$$

$$\begin{aligned}\hat{x}^+ &= A\hat{x} \\ P^+ &= APA^T + Q\end{aligned}$$

**Lyapunov Equation**  
(unstable)

$$\gamma = 1$$

$$\begin{aligned}\hat{x}^+ &= A\hat{x} + K_k^t(\tilde{y}_k^t - CA\hat{x}) \\ P^+ &= APA^T + Q - APC^T(CPC^T + R)^{-1}CPA^T\end{aligned}$$

**Riccati Equation**  
(stable)

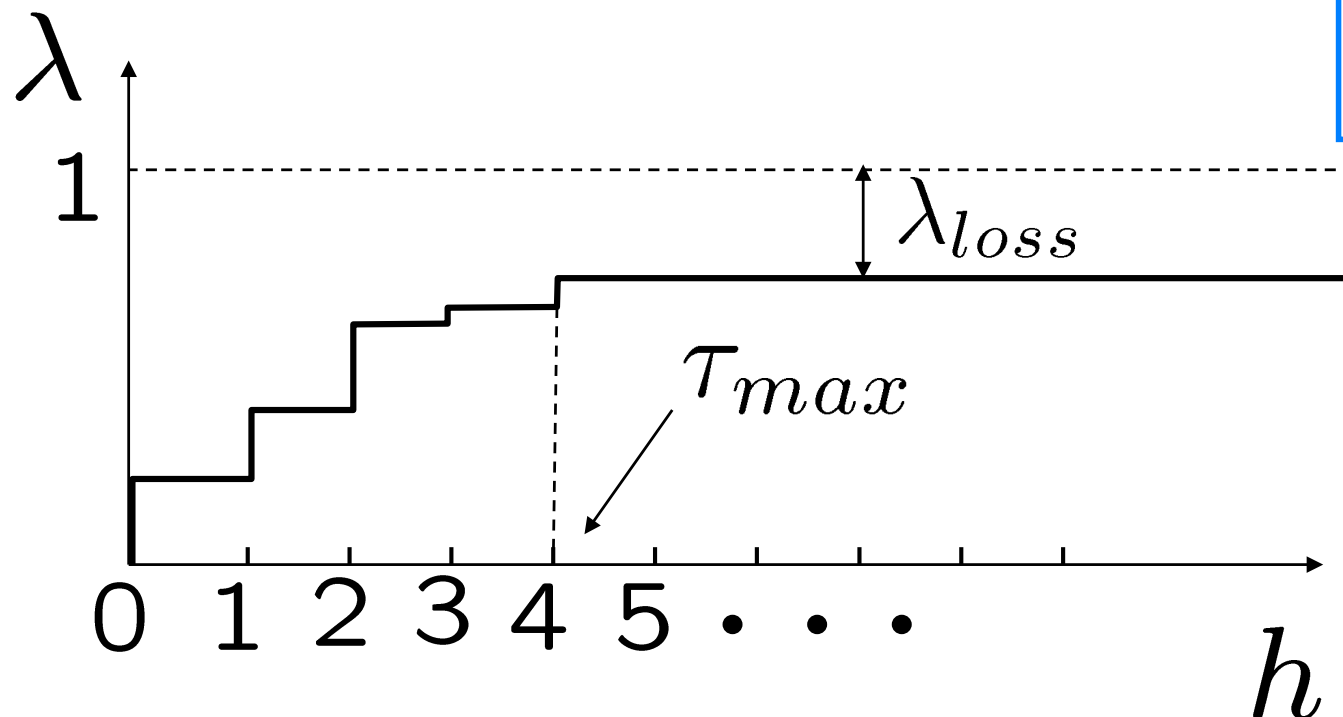

# What about stability and performance?

Additional assumption on arrival sequence necessary:  
**i.i.d. arrival with stationary distribution**

$\tau_k$  : delay of packet  $y_k$ ,  $\tau_k = \infty$  if  $y_k$  never arrives

$$\lambda_h \triangleq \mathbb{P}[\tau_k \leq h],$$

$$\lambda_{loss} \triangleq \mathbb{P}[\tau_k = \infty]$$

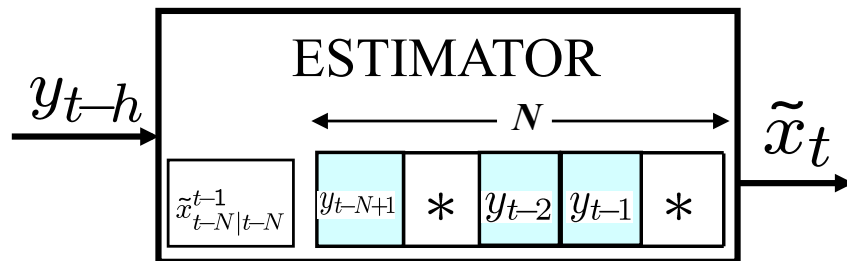

# Optimal estimation with constant gains and buffer finite memory

$\{K_h\}_{h=0}^{N-1}$ ,  $N$  static gains

$$\tilde{x}^+ = A\tilde{x} + \gamma_{t-h}^t K_h (\tilde{y}_{t-h}^t - CA\tilde{x}), \quad h = N - 1, \dots, 0$$

- Does not require any matrix inversion
- Simple to implement
- Upper bound for optimal estimator:
- $N$  is design parameter

$$P_t \leq \tilde{P}_{t|t} \implies \mathbb{E}_\gamma[P_{t|t}] \leq \mathbb{E}_\gamma[\tilde{P}_{t|t}] = \bar{P}_{t|t}$$

GOAL: compute  $\bar{P}_{t|t}$

# Suboptimal minimum variance estimation

# Suboptimal minimum variance estimation

# Steady state estimation error

## Fixed gains:

$$\mathcal{L}_\lambda(K, P) = \lambda A(I - KC)P(I - KC)^T A^T + (1 - \lambda)APA^T + Q + \lambda AKRK^T A^T$$

$$\bar{P} = \mathcal{L}_{\lambda_{N-1}}(K_{N-1}, \bar{P})$$

$$\bar{P}^+ = \mathcal{L}_{\lambda_k}(K_k, \bar{P}), \quad k = N-2, \dots, 0$$

$$\lim_{t \rightarrow \infty} \bar{P}_{t|t} = \bar{P}$$

## Optimal fixed gains:

$$\Phi_\lambda(P) = APA^T + Q - \lambda APC^T (CPC^T + R)^{-1} CPA^T$$

Modified Algebraic  
Riccati Equation (MARE)  
( $\Phi_1(P) = ARE$ )

$$\min_{K_0, \dots, K_{N-1}} \bar{P}$$

$$\bar{P}_{N-1} = \Phi_{\lambda_{N-1}}(\bar{P}_{N-1})$$

$$\bar{P}_k = \Phi_{\lambda_k}(\bar{P}_{k+1}), \quad k = N-2, \dots, 0$$

$$K_k = \bar{P}_k C^T (C\bar{P}_k C^T + R)^{-1}$$

**(off-line computation)**

# Stability issues

Static estimator is stable iff there exists  $P \geq 0$  such that:

$$P = APA^T + Q - (1 - \lambda) APC^T (CPC^T + R)^{-1} CPA^T$$

- If  $\lambda = 0$  then standard ARE
- Modified Riccati Algebraic Equation known since [Nahi TIF'69]
- If  $A$  is unstable then there exist critical probability: if  $\lambda < \lambda_c$  stable, if  $\lambda > \lambda_c$  unstable
- Upper bound  $\lambda_c \leq \frac{1}{\max |\text{eig}(A)|^2}$ . Equality if  $C$  invertible [Katayama TAC'76]
- Lower bound  $\lambda_c \geq \frac{1}{\prod_{unstable} |\text{eig}(A)|^2}$ . Equality if  $\text{rank}(C) = 1$  [Elia TAC'01, SCL'05]
- Closed form expression for  $\lambda_c$  not known for general  $(A, C)$

# Numerical example (I)

Discrete time linearized inverted pendulum:

$$A = \begin{bmatrix} 1.01 & 0.05 \\ 0.05 & 1.01 \end{bmatrix}, \quad C = [1 \quad 0], \quad R = 1, \quad Q = \begin{bmatrix} 0.01 & 0.01 \\ 0.01 & 1 \end{bmatrix}$$

## Time-varying arrival probability distribution

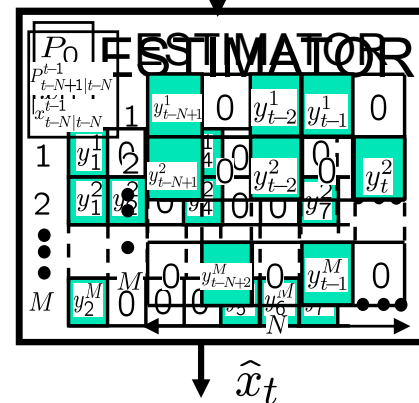

$$\lambda^1 \quad 0 \leq t \leq 50$$

$$\lambda^2 \quad t > 50$$

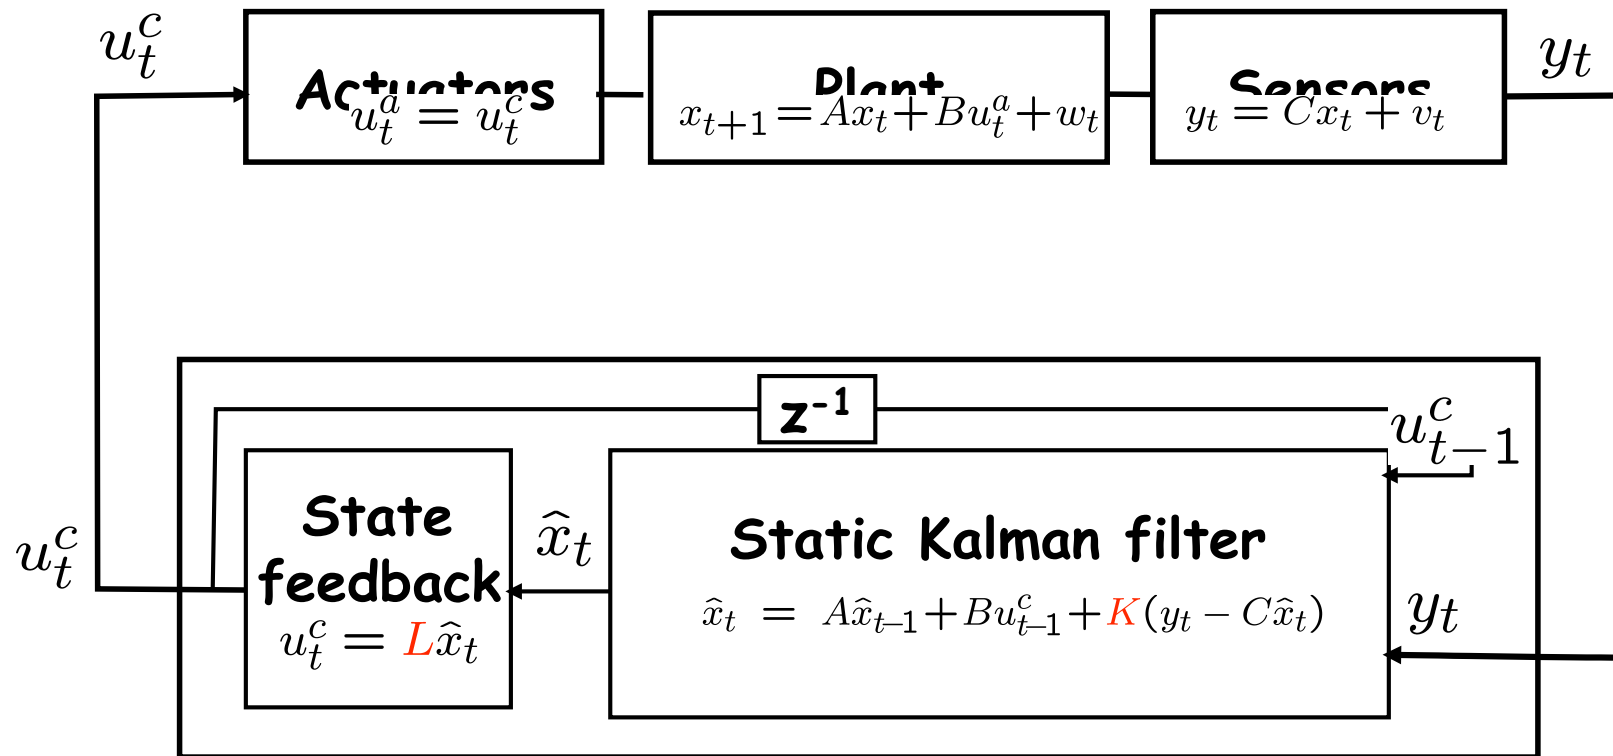

# Multiple sensors

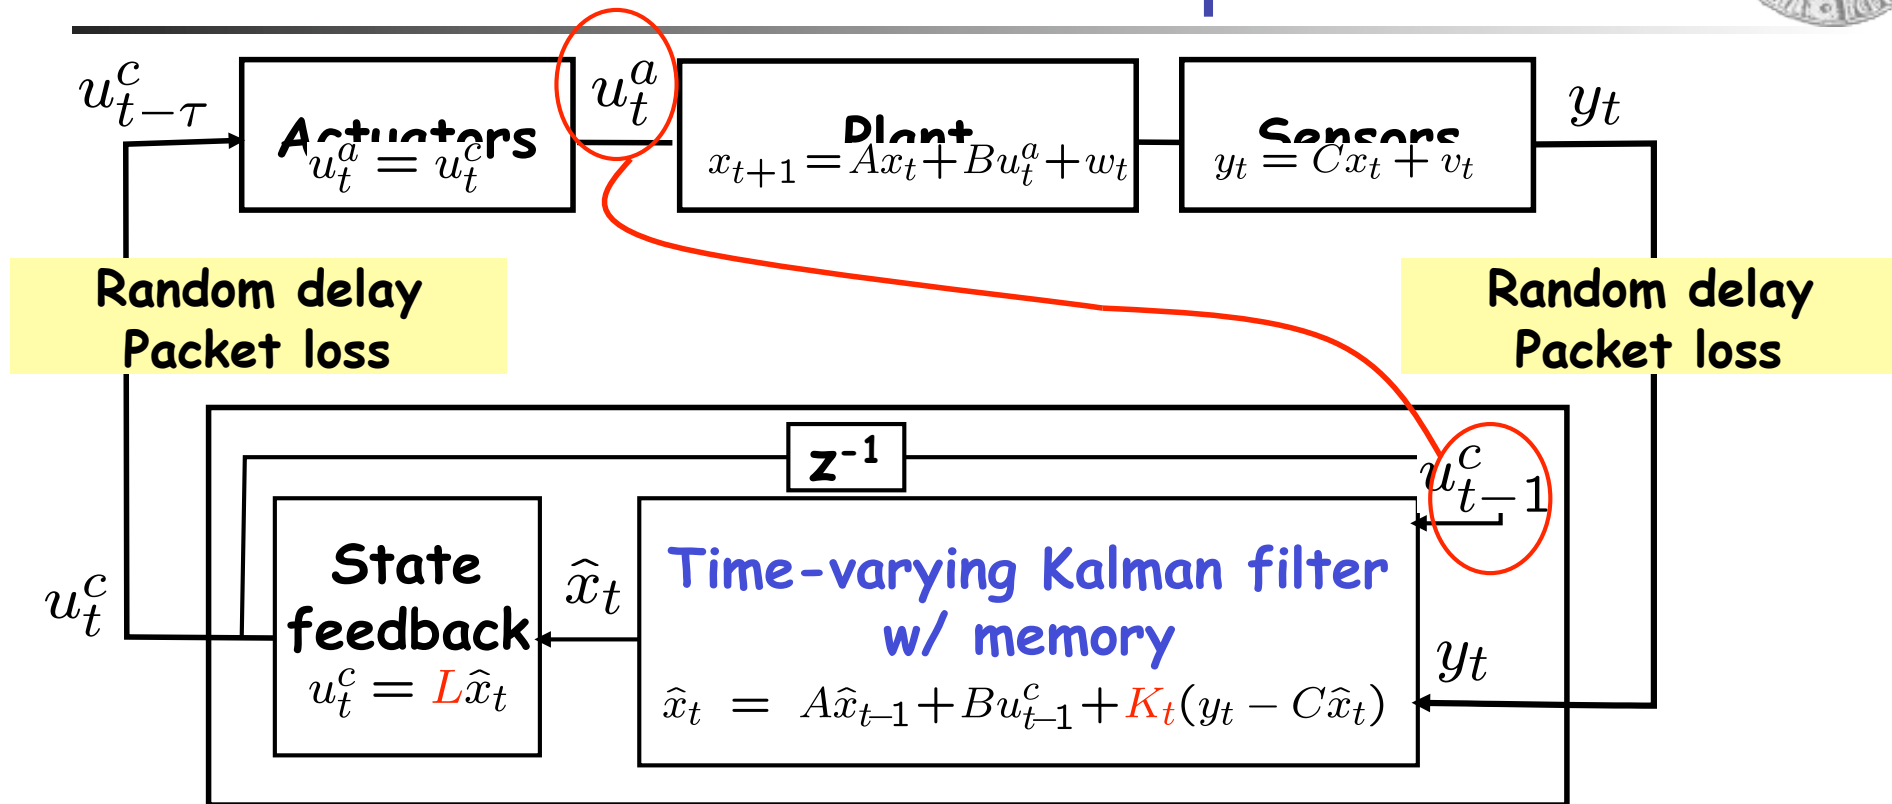

# Back to the control problem

# Back to the control problem

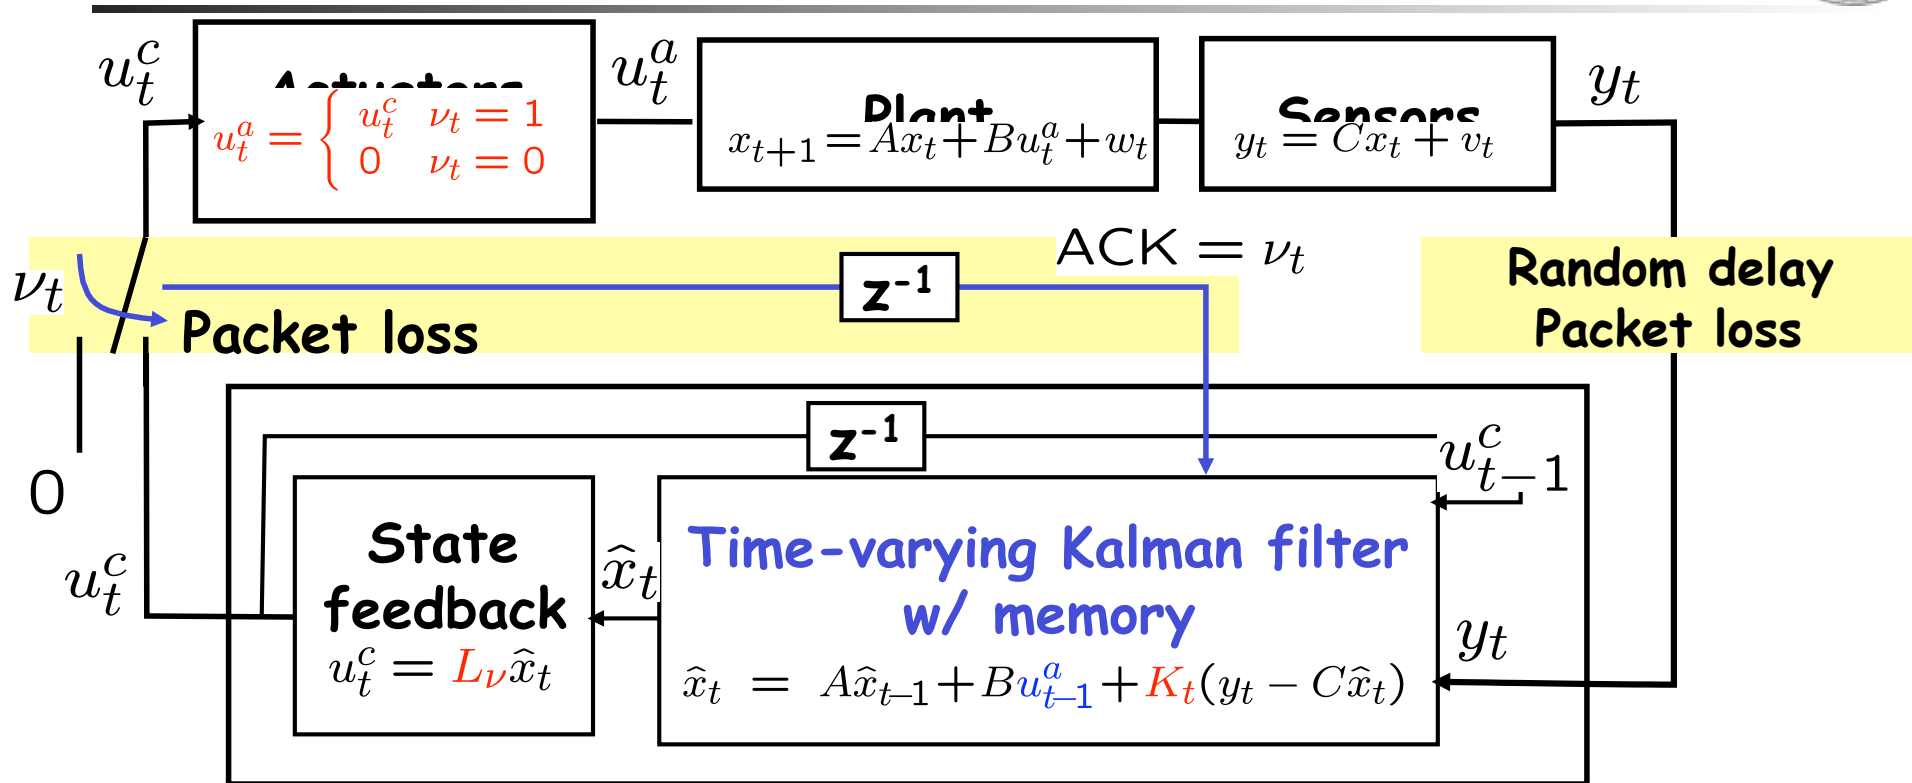

$$\hat{x}_t = E[x_t | y_t, y_{t-1}, \dots, y_0, u_{t-1}^a, \dots, u_1^a]$$

$$\text{if } u_{t-1}^c \neq u_{t-1}^a \implies e_t = x_t - \hat{x}_t = f(y_t, \dots, y_0, u_t^c, \dots, u_0^c, u_t^a, \dots, u_0^a)$$

$$P_{t|t-1} = AP_{t-1|t-1}A^T + Q + B(u_{t-1}^a - u_{t-1}^c)(u_{t-1}^a - u_{t-1}^c)^T B^T$$

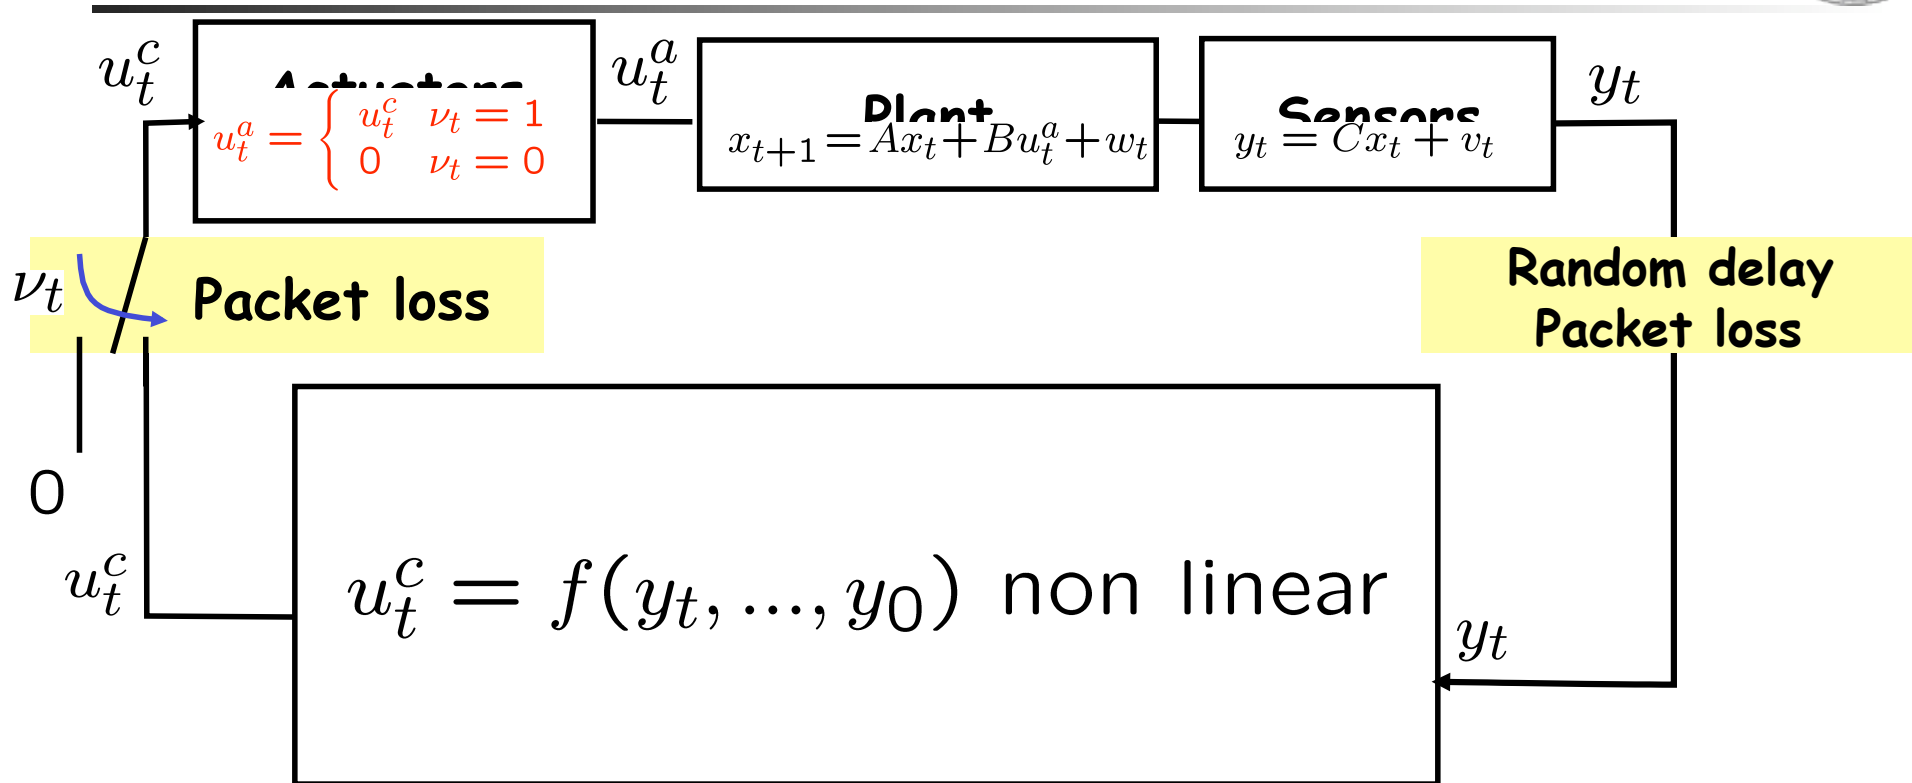

Estimation error coupled with control action  $\rightarrow$  no separation principle

# LQG over TCP-like (ACK-based) protocols

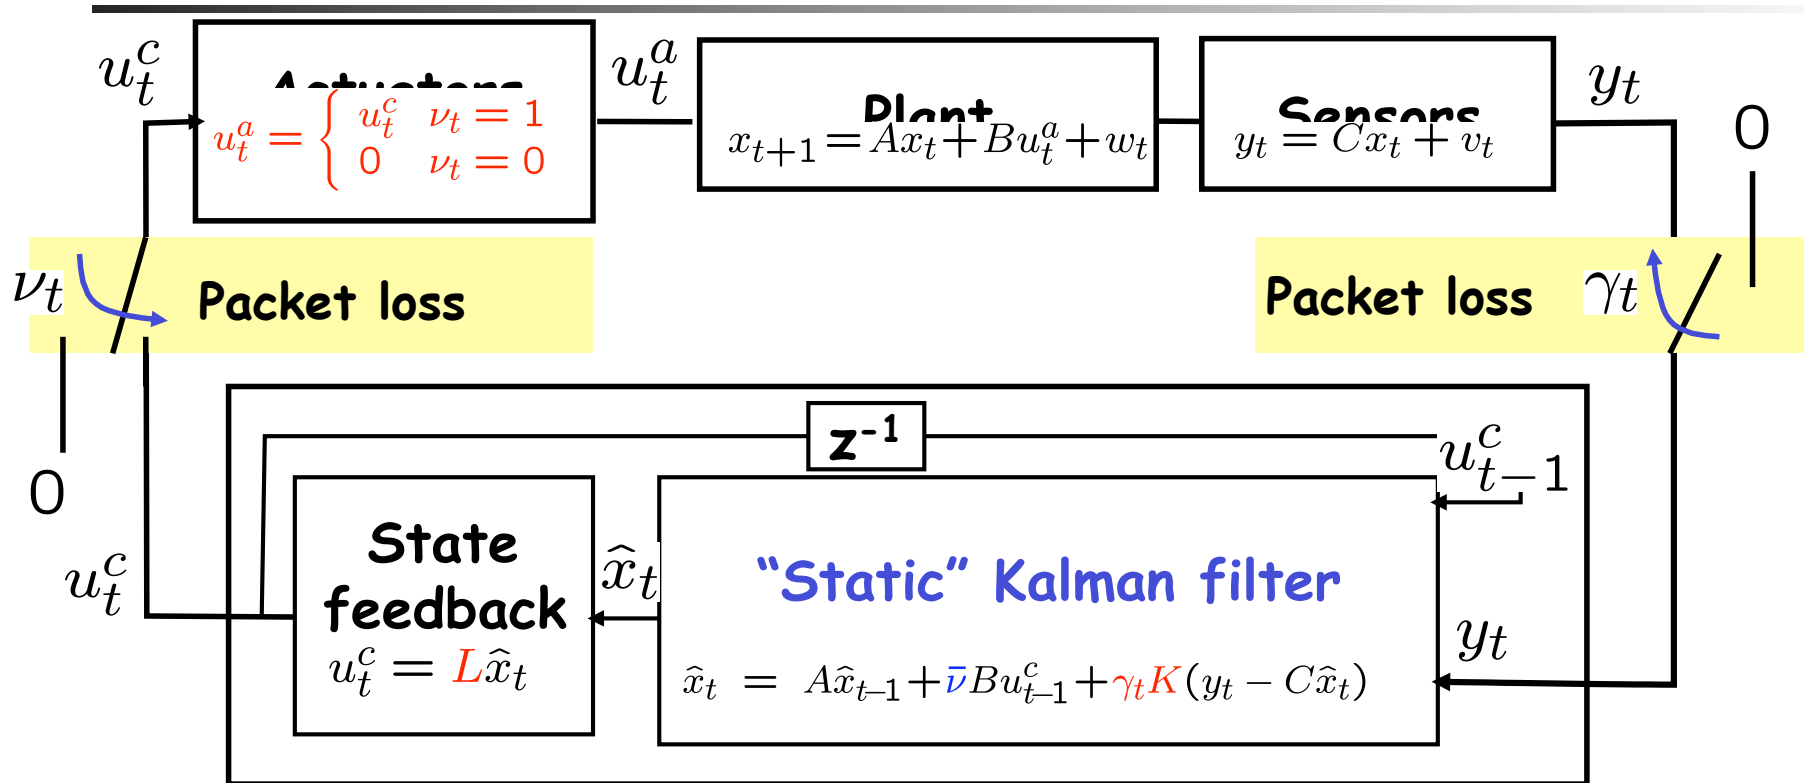

- Separation principle hold (I know exactly  $u_{t-1}^a$ )
- $\nu_t$  Bernoulli rand. var and independent of observation arrival process
- Static state feedback,  $L_\nu$  solution of dual MARE

# LQG over UDP-like (no-ACK) protocols

- LQG problem still well defined:  $\min_{u_t^c, \dots, u_1^c} E[\sum_{h=1}^t x_h^T W x_h + (u_h^a)^T U u_h^a]$
- No separation principle hold ( $u_{t-1}^a$  NOT known exactly)
- ... but still have some statistical information about  $u_{t-1}^a$

# LQG over UDP-like (no-ACK) protocols

- Bernoulli arrival process  $P[\nu_t = 1] = \bar{\nu}, P[\gamma_t = 1] = \bar{\gamma}$
- $\bar{\nu}u_{t-1}^c = E[u_{t-1}^a]$
- Sub-optimal controller forced to be state estimator+state feedback
- Optimal choice of  $K, L$  is unique solution of 4 coupled Riccati-like equations

# LQG as optimization problem

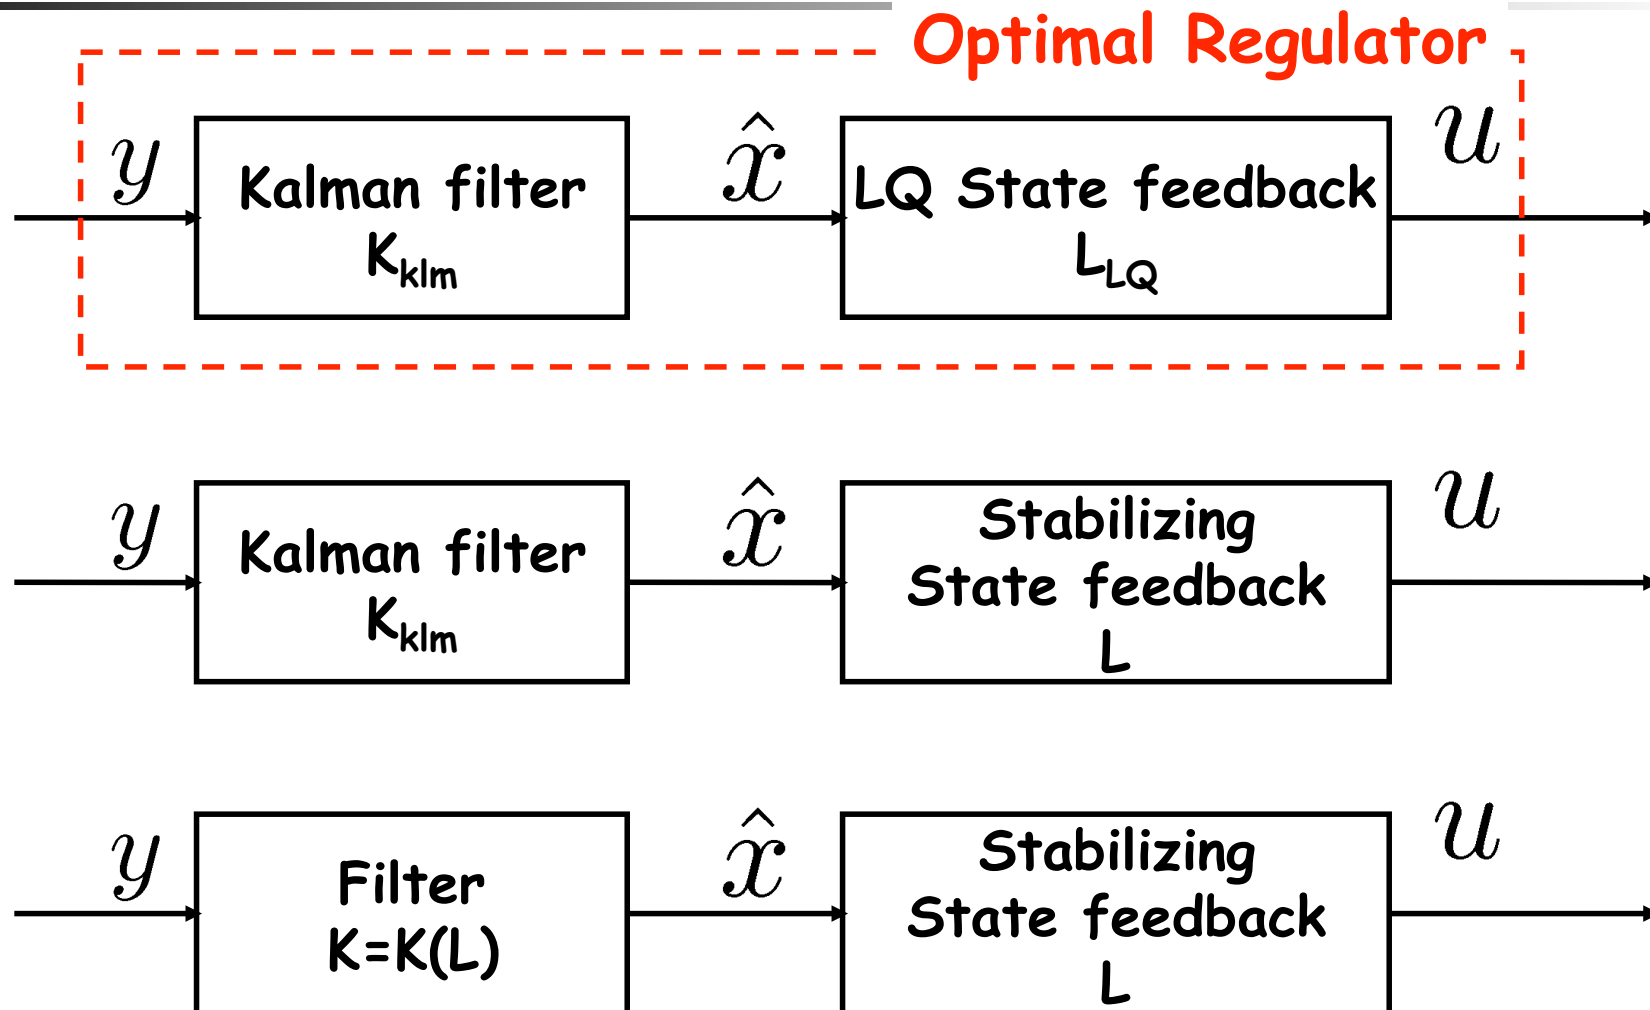

$$\begin{aligned} \text{Min}_{K,L} \quad & \text{Trace} \left( \begin{bmatrix} W & 0 \\ 0 & \bar{\nu} L^T U L \end{bmatrix} P \right) \quad P \triangleq \mathbb{E} \left[ \begin{bmatrix} x \\ \hat{x} \end{bmatrix} \begin{bmatrix} x^T & \hat{x}^T \end{bmatrix} \right] = \begin{bmatrix} P_{11} & P_{12} \\ P_{12}^T & P_{22} \end{bmatrix} \\ \text{s.t.} \quad & P = \mathbb{E} \left[ \begin{bmatrix} A & -\nu_k B L \\ \gamma_k K C & A - \bar{\nu} B L - \gamma_k K C \end{bmatrix} P \begin{bmatrix} A & -\nu_k B L \\ \gamma_k K C & A - \bar{\nu} B L - \gamma_k K C \end{bmatrix}^T \right] + \begin{bmatrix} Q & 0 \\ 0 & \bar{\gamma} K R K^T \end{bmatrix} \\ & P \geq 0 \end{aligned}$$

- Non convex problem even for  $\nu=\gamma=1$ , i.e. classic LQG
- Classic and TCP-based LQG become convex when exploiting optimality conditions like uncorrelation between estimate and error estimate  $\mathbb{E}[x(x - \hat{x})^T] = 0$
- For UDP-like problem non convex but unique solution using Homotopy and Degree Theory (DeKoning, Athans, Bernstein) (maybe using Sum-of-Squares?)
- Stability on  $\nu$  and  $\gamma$  is coupled

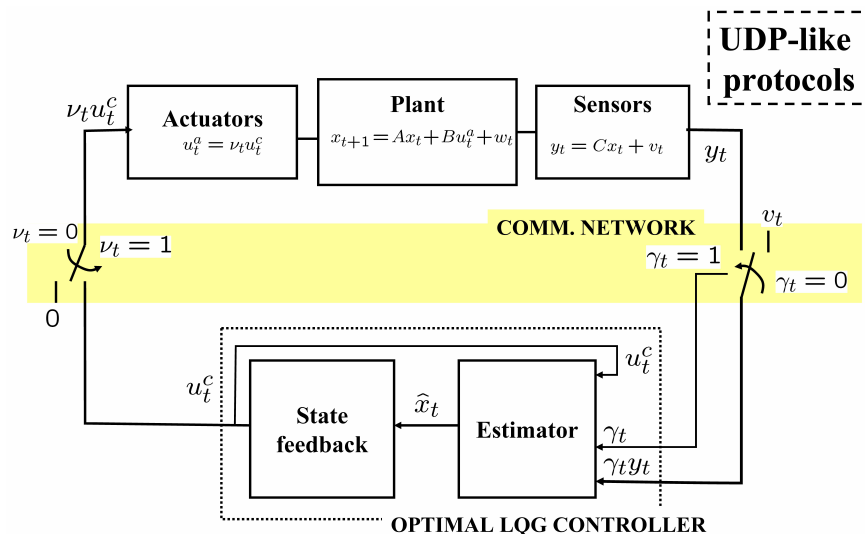

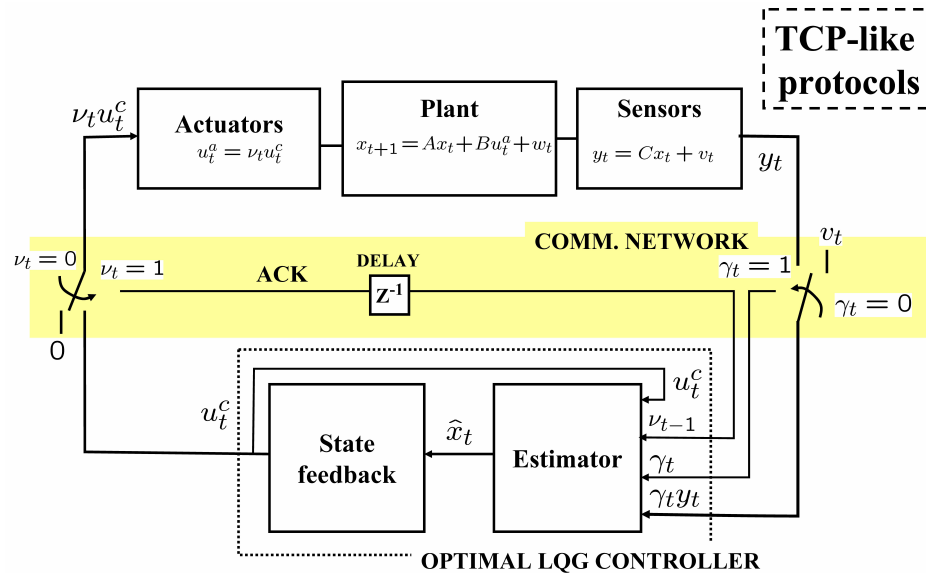

# Side note: Kalman filter is not always optimal !

- Kalman filter always gives smallest estimate error **regardless** of controller  $L$
- If controller  $L \neq L_{LQ}$ , then performance improves if my estimate is "bad" !

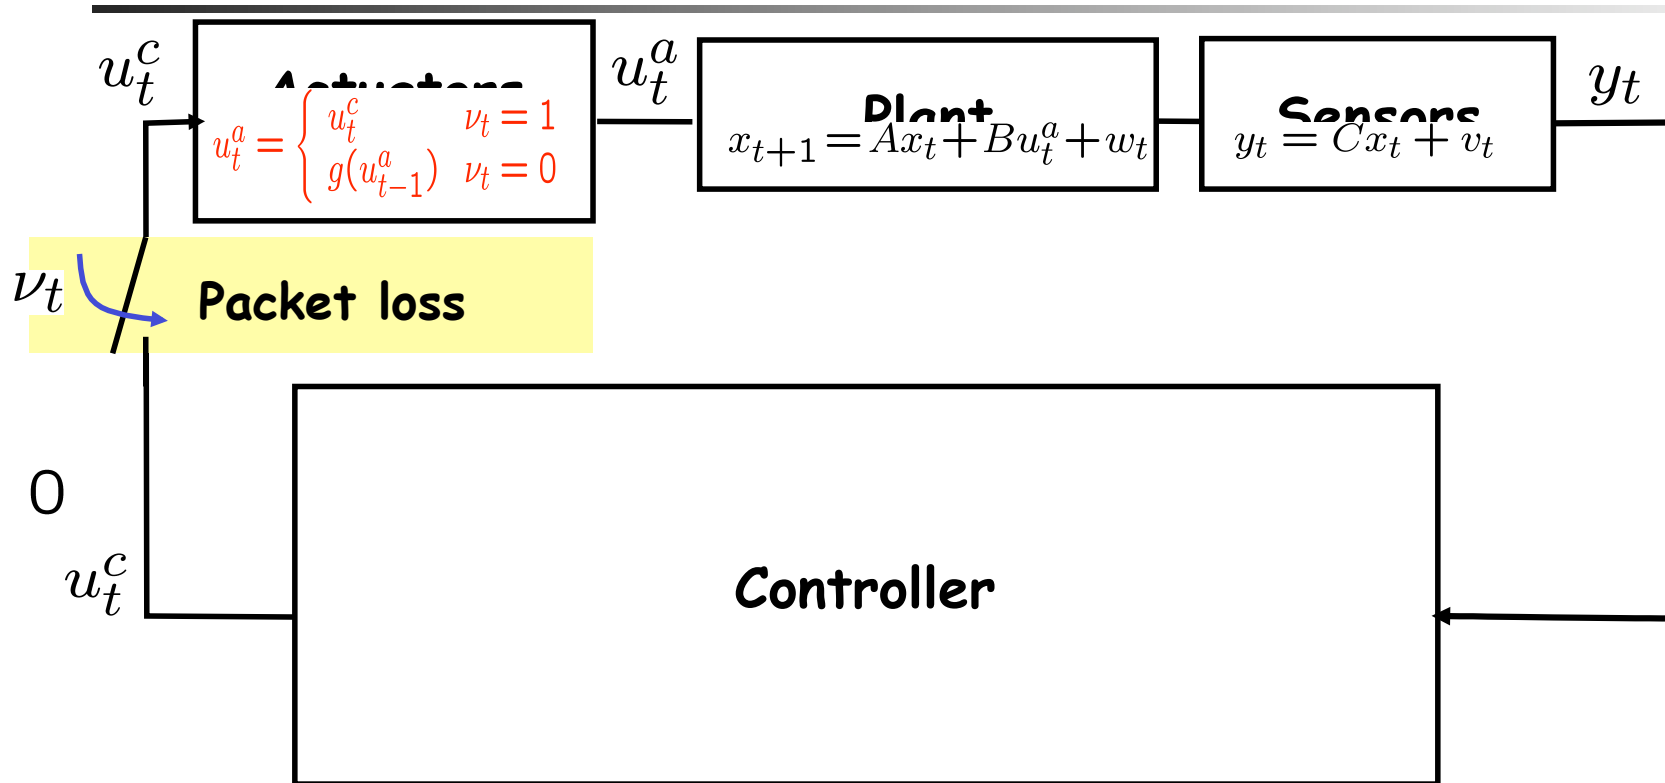

# Numerical example: TCP vs UDP

# To hold or to zero control input?

Most common strategy:

- $g(u_{t-1}^a) = 0$  zero-input strategy (mathematically appealing)
- $g(u_{t-1}^a) = u_{t-1}^a$  hold-input strategy (most natural)

# To hold or to zero control input: no noise (jump linear systems)

## Zero-input Strategy

$$J_z^* = \min_{L_z} E[\sum_{t=1}^{\infty} x_t^T W x_t + (u_t^a)^T U u_t^a]$$

## Hold-input Strategy

$$J_h^* = \min_{L_h} E[\sum_{t=1}^{\infty} x_t^T W x_t + (u_t^a)^T U u_t^a]$$

## Using cost-to-go function (dynamic programming)

$$J_z^* = E[x_0^T S_z x_0]$$

$$J_h^* = E[x_0^T S_h x_0]$$

$$S_z = \Phi_z(S_z) \longleftarrow \text{Riccati-like equation} \longrightarrow S_h = \Phi_h(S_h)$$

$$L_z^* = f_z(S_z)$$

$$L_h^* = f_h(S_h)$$

# Example: unstable scalar system

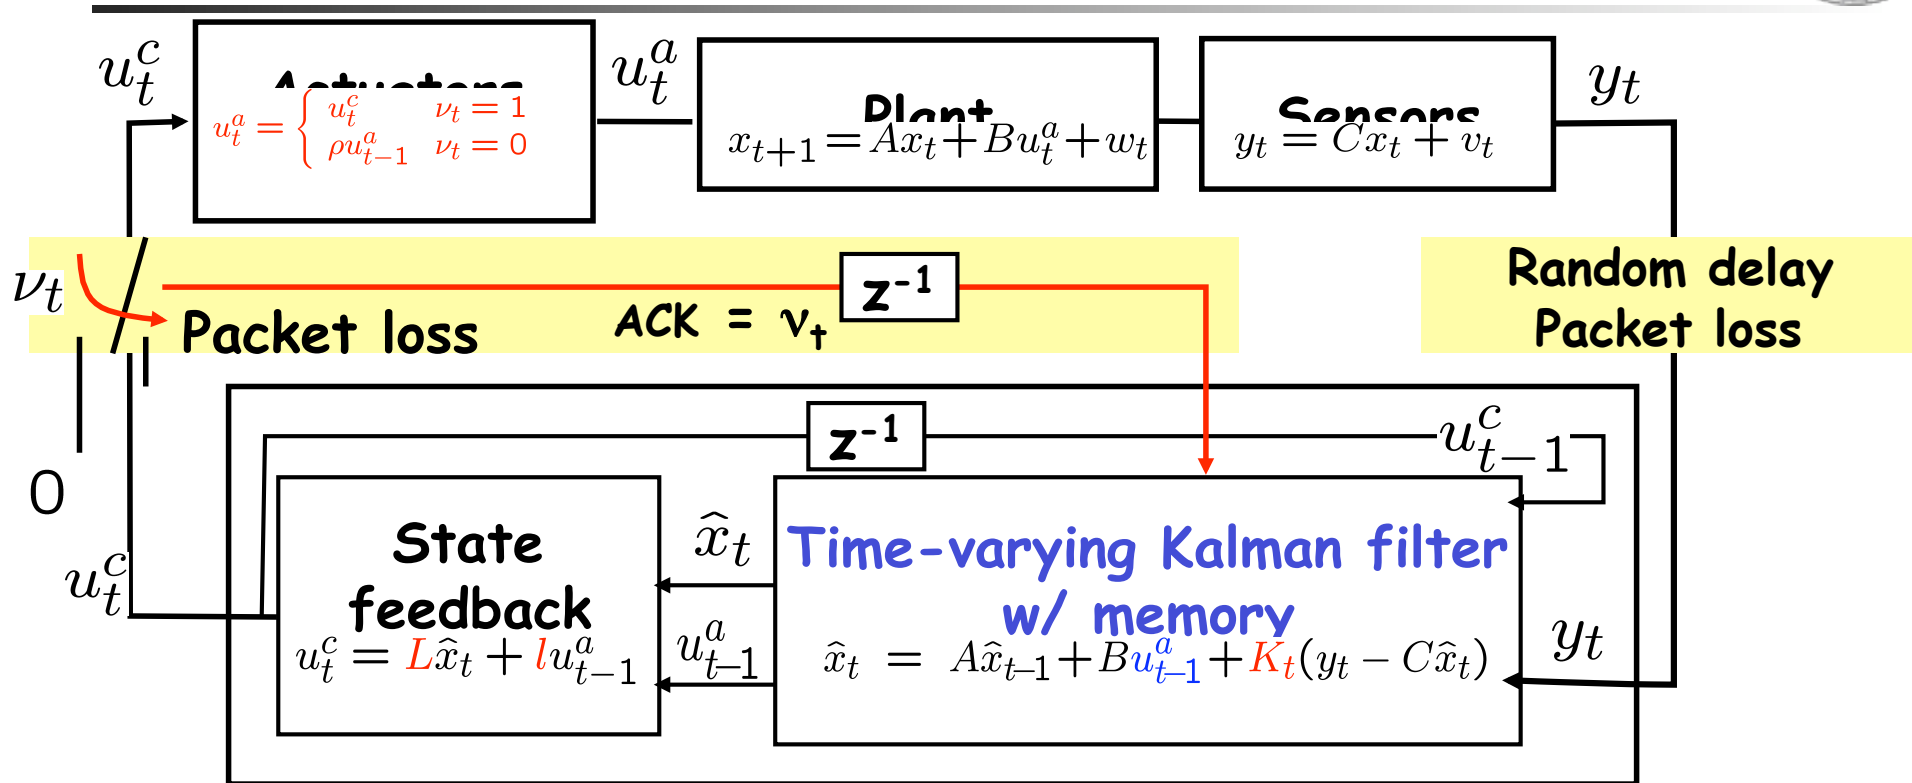

$A=1.2, U=0$  (fastest convergence)

$A=1.2, U=10$  (small input)

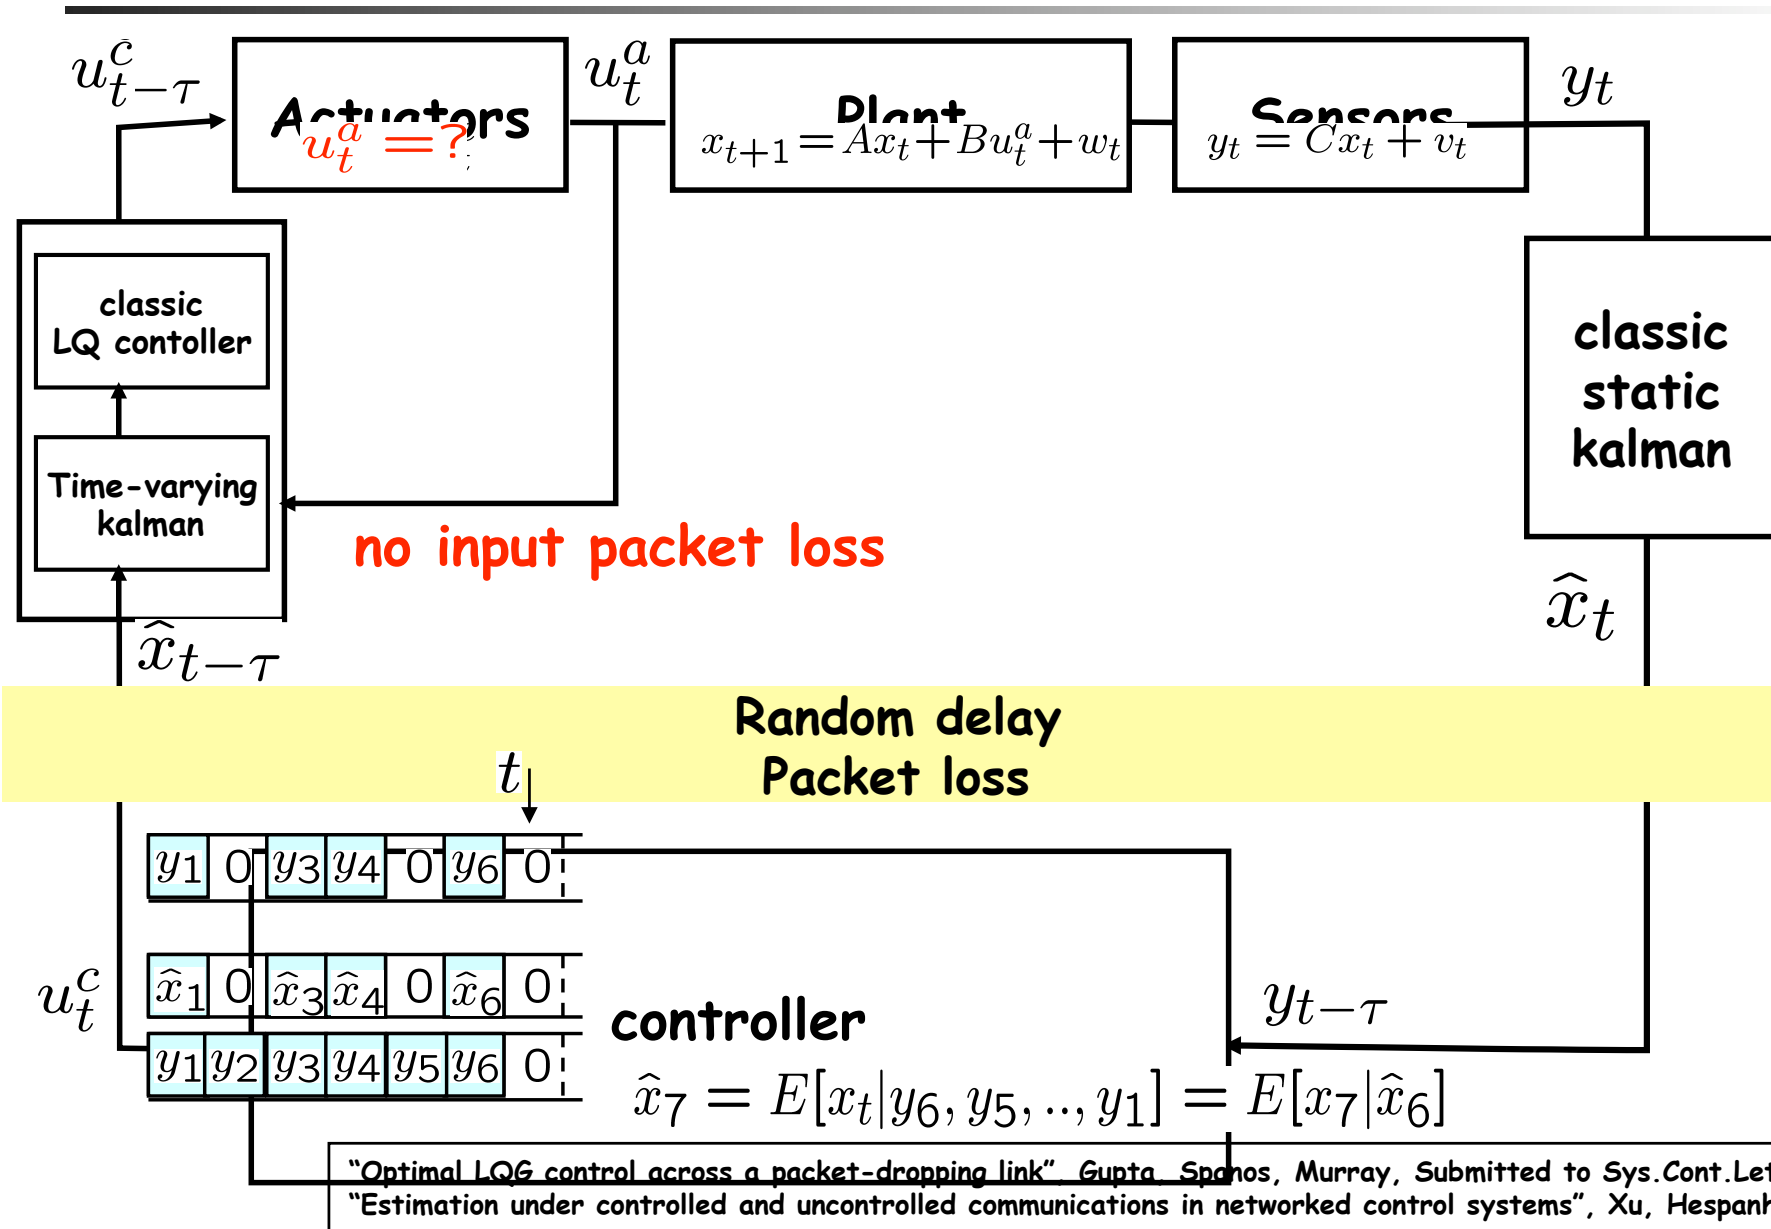

# LQG over TCP-like protocols revised

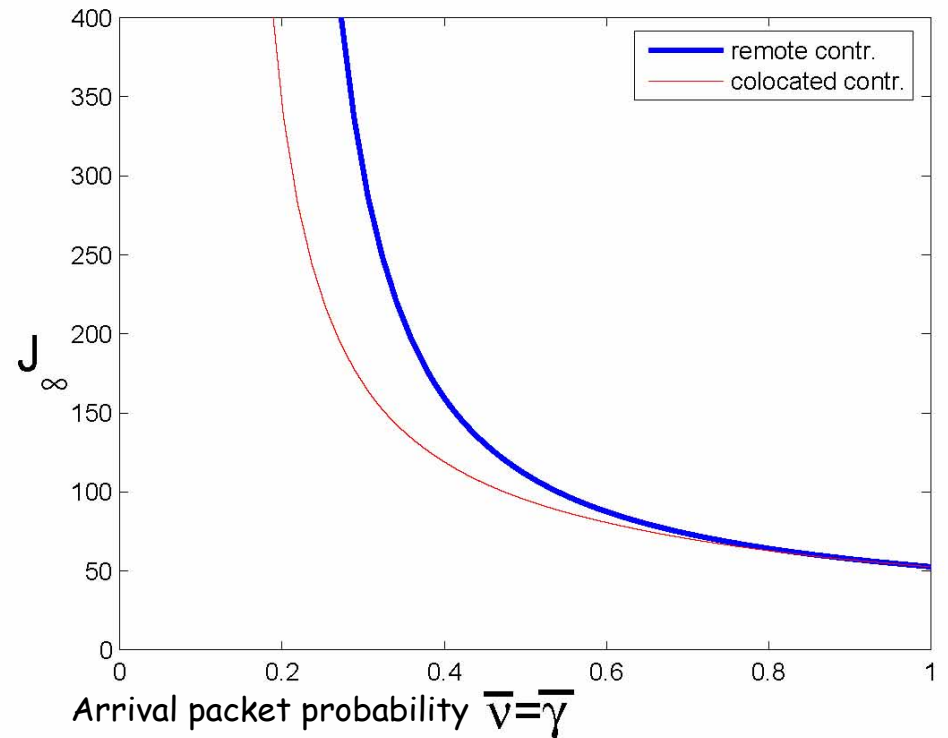

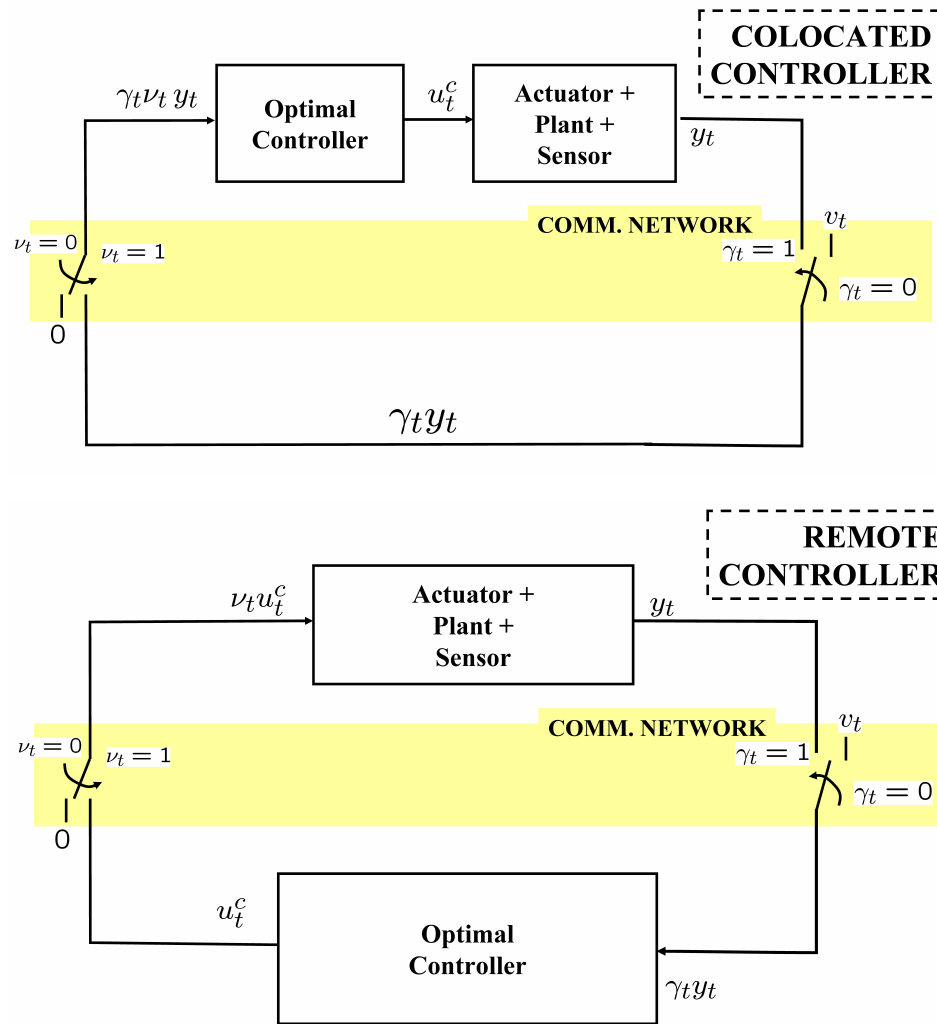

## Conjecture:

- Separation principle hold
- Optimal function  $g(u_{t-1}^a) = \rho u_{t-1}$
- Design parameter  $L, l, \rho$  obtained via LQ-like optimal state feedback

# Smart sensors & smart actuators

# Numerical example: remote vs co-located controller

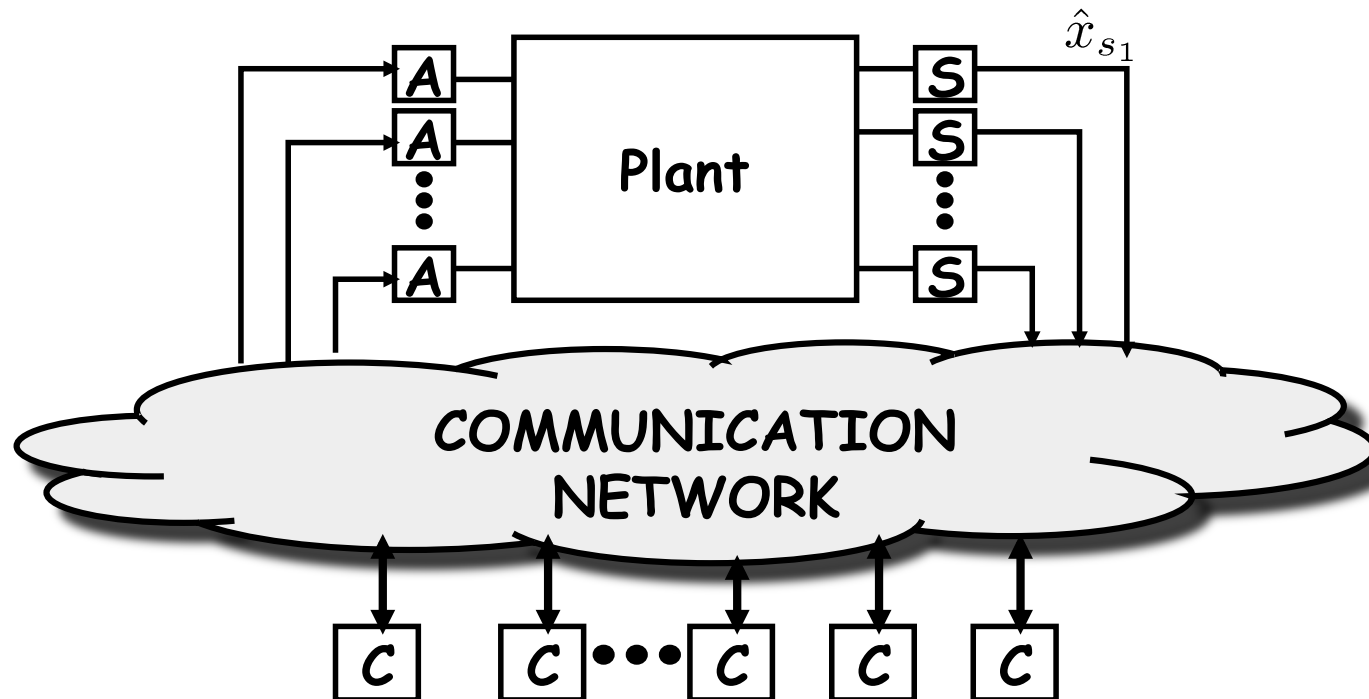

# Takeaway points

- Input packet loss more dangerous than measurement packet loss
- TCP-like protocols help controller design as compared to UDP-like (but harder for communication designer)
- If you can, place controller near actuator
- If you can, send estimate rather than raw measurement
- Zero-input control seems to give smaller closed loop state error ( $\|x_t\|$ ) than hold-input (but higher input)
- Trade-off in terms of performance, buffer length, computational resources (matrix inversion) when random delay
- Can help comparing different communication protocols from a real-time application performance

# Future work

- Multiple sensors:
  - data fusion, i.e.  $y_1, \dots, y_m$  arrive at different times
  - distributed estimation & consensus  $E[x|y_1, \dots, y_N] \stackrel{?}{=} E[x|\hat{x}_{s_1}, \hat{x}_{s_N}]$
- Multiple actuators
  - trade-off between distributed control & centralized coordination

# Distributed sensor fusion & Consensus-based estimation
